(54) OPTICAL DATA RECORDING MEDIUM, METHOD OF PRODUCING THE SAME AND METHOD OF REPRODUCING/ERASING RECORD

(57) In a phase-change recording medium, a recording medium is provided with a barrier layer including Ge-N, Ge-N-O between a recording layer and a dielectric protective layer in order to prevent a chemical reaction and an atom diffusion between the recording layer and the dielectric protective layer. A barrier material can be also applied to the protective layer itself. Thereby, it is possible to considerably suppress a reduction of a reflectivity and a reduction of a signal amplitude due to the repeat of recording and erasing, such reductions being observed in a conventional phase-change optical information recording medium, and thereby the number of overwriting times can be increased.

Fig. 2

EP 0 825 595 A1

Description

TECHNICAL FIELD

The present invention relates to an optical information recording medium provided with an optically detectable information recording layer, the producing method thereof and a method of recording/erasing/reproducing information.

BACKGROUND ART

A recording material thin film layer comprising a metal thin film and an organic thin film is formed on a disc-shaped or a card-shaped substrate. A high energy beam focused on a micro light spot having a submicron order diameter is irradiated onto the recording material layer, thereby a local variation is generated on recording material layer. Thereby, such a technique that an information signal is stored is already well known. More specifically, when an optical magnetic material thin film and a phase change material thin film are used for a recording layer, it is easy to rewrite the signal. Accordingly, this technique has been actively studied and developed. For example, in case of the optical magnetic recording medium, a difference of a rotating angle on a polarized surface of a reflected light generated due to the difference of a magnetization state is used as the record. Furthermore, in case of the phase change recording medium, an amount of a reflected light relative to a light having a specific wavelength in a crystalline state is different from that in an amorphous state, thereby the difference is used as the record. A laser output is modulated between a record level having a relatively higher power and an erasure level having a relatively lower power, and the modulated output is only irradiated on a recording medium. Thereby similarly to a magnetic disk, there is such a characteristic that the record erasure and the record of a new signal can be simultaneously performed (it is possible to overwrite the record). The information signal can be rewritten for a short time.

Usually, the optical magnetic recording medium and the phase change recording medium comprise, for example, a multi-layer film shown in FIG. 1. That is, on a substrate 1 comprising a resin plate of a polycarbonate and PMMA (polymethyl-methacrylate), a glass plate, or the like, usually, a recording layer 3 having an optical absorption comprising the phase change material and the optical magnetic material inserted between protective layers 2 and 4 comprising a dielectric material is formed. Furthermore, a metallic reflecting layer 5 comprising an alloy of Au and Al for increasing an optical absorption efficiency on the recording layer 3 and for acting as a thermal diffusion layer is formed on the protective layer 4. These layers are sequentially laminated by a sputtering method, a vacuum deposition method, or the like. Furthermore, an overcoat layer 6 is formed on an uppermost layer in such a manner that a scratch and dusts are not attached to these layers. Usually, a laser beam is incident from a side of the substrate 1. In many cases, a front surface of the substrate 1 is provided with a concave-convex groove track or a concave-convex pit sequence as guide means for guiding the laser beam to a predetermined position on the disk.

A function of each layer and an concrete example of materials forming each layer are as follows.

In case of the recording layer 3, when the phase change material is used, chalcogenite thin film whose base comprises Te and Se, for example, a Ge-Sb-Te alloy thin film, a Ge-Sb-Te-Se alloy thin film, an In-Sb-Te alloy thin film, an Ag-In-Sb-Te alloy thin film, an In-Se alloy thin film, and the like are reported. In the medium using such phase change materials, the laser beam is irradiated, thereby the signal is recorded and reproduced. As already described, while the power of the laser beam is being modulated at a strong level and a weak level, the laser beam is irradiated onto a revolving recording medium. A portion irradiated with the strong power is locally melt in an instant, thenceforth, the portion is quenched. Thereby the portion is amorphized, and the signal is recorded. Furthermore, at the portion irradiated with a relatively weak power, the amorphous-state portion is annealed, thereby the portion is crystallized, and the recorded signal is erased. In order to reproduce the signal, the power of the laser beam is reduced enough in such a manner that the recording film is not changed, and the laser beam is irradiated. At this time, a strength of the reflected light is detected, and whether the portion irradiated with the laser beam is in the crystalline state or the amorphous state is judged, thereby the signal is reproduced.

The functions of the protective layers 2 and 4 comprising a dielectric material are, for example, as follow:

- 1) the recording layer is protected from an external mechanical damage;
- 2) a thermal damage such as a roughness on the surface of the substrate, a break of the recording layer and an evaporation, etc. occurred due to repeatedly rewriting the signal are reduced, thereby a repetition of rewriting the signal can be increased;
- 3) an interference effect of a multipath reflection is used so that an optical change can be enhanced;
- 4) an influence from an outside air is intercepted so that a chemical change can be prevented.

As the material comprising the protective layer for satisfying the above objects, heretofore, an oxide such as SiO_2 , Al_2O_3 or the like, a nitride such as Si_3N_4 , AlN or the like, an acid nitride such as Si-O-N or the like (for example, dis-

closed in Japanese Patent Application Laid-open No. 3-104038), a sulfide such as ZnS or the like, a carbide such as SiC or the like, or a mixed material such as ZnS-SiO₂ or the like (disclosed in Japanese Patent Application Laid-open No. 63-103453) is proposed, and one part of them is practically used.

Two layers are provided to the protective layer, thereby the characteristic thereof can be enhanced. The example of the phase change recording medium is disclosed in Japanese Patent Application Laid-open No. 5-217211. That is, the dielectric layer comprising the nitride (SiN, AlN) and the carbide (SiC) is used at the side contacted to the optical recording layer as the protective layer of the optical recording layer including Ag, and ZnS or a compound including ZnS is used as the outer layer of the dielectric layer. The above SiN, SiC, AlN layer is used, thereby a combination of Ag included in the recording layer and S in the protective layer is prevented. As disclosed in Japanese Patent Application Laid-open No. 5-217211, a film thickness of the SiN, AlN, SiC layer is ranging from 5 nm to 50 nm. Furthermore, as disclosed in Japanese Patent Application Laid-open No. 6-195747, the protective layer has two layers inserted between the recording layer and the substrate, where one layer contacted to the recording layer comprises Si₃N₄ layer and the other layer contacted to the substrate comprises ZnS-SiO₂ layer, thereby two dielectric layers are formed. The Si₃N₄ layer facilitates a crystallization of the phase change material layer.

The example of the optical magnetic recording medium is disclosed in Japanese Patent Application Laid-open No. 4-219650. Here, the dielectric layer contacted to the substrate has two layers, and one layer contacted to the substrate is a silicon oxide film, thereby an adhesiveness of the substrate and the dielectric layer is enhanced. Furthermore, the other layer contacted to the recording layer comprises the compound of the carbide and the nitride, thereby it is possible to prevent a corrosion of the magnetic recording layer occurred due to that oxygen from the silicon oxide layer and water passing through the substrate are penetrated into the recording layer. As disclosed in Japanese Patent Application Laid-open No. 4-219650, preferably, the nitride comprises Sn-N, In-N, Zr-N, Cr-N, Al-N, Si-N, Ta-N, V-N, Nb-N, Mo-N and W-N, and the film thickness thereof is ranging from 10 nm to 20 nm. Furthermore, as disclosed in Japanese Patent Application Laid-open No. 4-321948, in the same view of Japanese Patent Application Laid-open No. 4-219650, the dielectric layer contacted to the substrate has two layers. Here, one layer near the substrate comprises one or more kind of oxide selected from a group of Si, Zr, Y, Mg, Ti, Ta, Ca and Al, thereby the adhesiveness of the dielectric layer and the substrate is enhanced. Furthermore, the other layer contacted to the optical magnetic recording film comprises the nitride layer comprising one or more kind of nitride selected from the group of Si, Zr, Y, Mg, Ti, Ta, Ca and Al, thereby it is suppressed that oxygen and water from the oxide layer are penetrated and diffused into the recording film layer. As disclosed in Japanese Patent Application Laid-open No. 4-321948, the film thickness of the nitride layer is ranging from 50 nm to 200 nm.

In general, the reflecting layer 5 comprises a metal such as Au, Al, Cr, Ni, Ag or the like and the alloy based upon these metals, and the reflecting layer 5 is disposed in such a manner that a radiation effect and an effective optical absorption of the recording thin film can be obtained.

As described above, in general, a sputtering method, a vacuum deposition method or the like is used as the method of preparing the recording medium. Furthermore, a reactive sputtering method is used so that the nitride can be contained in the thin film.

For example, as the method of producing an ablation type write once medium, such a method that N is contained in the Te-containing recording layer by the reactive sputtering is disclosed in Japanese Patent Application Laid-open No. 63-151486. As disclosed in Japanese Patent Application Laid-open No. 63-151486, a mixed gas of Ar and nitride is discharged relative to a telluric selenium alloy target. After the recording film containing tellurium, selenium and nitride on the substrate is formed by the reactive sputtering method, a nitrogen gas is introduced, and a nitrogen plasma is generated, thereby a surface layer having a high nitrogen density than an inside of the recording layer is formed. The surface of the recording film is nitrided, thereby a weather-proofness and a sensitivity are enhanced, and further a power tolerance is increased. The nitrogen density of the nitride layer is ranging from 2% to 10%, preferably, it is ranging from 2% to 20%. Preferably, the thickness of the surface layer is ranging about from 1 nm to 10 nm.

Furthermore, the example of the ablation type recording material is also disclosed in Japanese Patent Application Laid-open No. 63-63153. The target comprising a material containing Te and Se is sputtered in a nitriding-oxide gas, a nitric dioxide gas or a gas containing a nitric dioxide, thereby the layer containing Te, Se and N is formed in the recording layer.

Furthermore, as disclosed in Japanese Patent Application Laid-open No. 4-78032, the surface of a metallic target is sputtered by Ar gas, and on the surface of the metallic element substrate is reacted with oxygen gas or nitrogen gas, thereby a metallic oxide film or a metallic nitride film is formed.

Furthermore, although omitted in the drawings, in order that an oxidization of the optical information recording medium or an attachment of dusts, etc. is prevented, such a structure that the overcoat layer is placed on the metallic reflecting layer 5, such a structure that an ultraviolet curing resin is used as an adhesive so that a dummy substrate is laminated, or the like is proposed.

However, it is known that the phase change optical recording medium has the following problems. That is, when the thin film comprising a material whose base is Te, Se, etc. containing Ge, Sb, In, etc. is used as the recording layer, and

further the thin film comprising an oxide system material including such as SiO_2 representatively, the thin film comprising a sulfide system material including such as ZnS representatively, or the thin film comprising a mixture system material including ZnS-SiO_2 between the above two thin films is used as the protective layer, a laser irradiation is carried out. Thereby, the record and erasure of the information signal, and the like are repeated, thereby optical characteristics of the recording layer and the protective layer (such as a reflectivity, an absorptivity and the like) are changed. Accordingly, such a phenomenon that a recording characteristic or an erasure characteristic is changed. That is, the signal is repeatedly rewritten, thereby the reflectance of the medium is reduced, an amplitude of the signal is gradually reduced, or a jitter value at a marked position of a recording mark becomes larger, thereby an error rate of the recording signal becomes higher. Therefore, when the signal is reproduced, a readout error is occurred. Accordingly, there is such a problem that a possible times of rewriting is limited.

Principal causes of this change are as follows. That is, one cause is that an S component and an O component are diffuse and penetrate from the protective layer to the recording layer, on the contrary, the component such as Te, Se, etc. having a relatively high vapor pressure among the components which the recording layer consists of diffuse from the recording layer to the protective layer. Furthermore, another cause is that one part of the protective layer material is chemically reacted with the recording layer. It is considered that the change is occurred due to either of the above causes, or a combination of the above causes.

In fact, according to an experiment by inventors, etc., in the optical disk applying a Ge-Sb-Te recording film and a ZnS-SiO_2 protective layer, the S component is discharged from the protective layer due to the laser irradiation. Consequently, it is observed that an S atom is penetrated from the protective layer to the recording layer. Furthermore, it is also observed that the other Zn atom, Si atom and O atom are also diffused to the recording layer. In this case, although it is assumed that other elements are easy to move by a separation of the S atom, the mechanism thereof is not clear.

The phenomenon and the mechanism have not been clearly reported. In case that the nitride thin film including Si_3N_4 and AlN is used as the protective layer, the S component is not discharged, differently from the above example. On the other hand, an adherence to the recording layer of such a nitride is lower than that of ZnS-SiO_2 film. For example, under an environment having a high temperature and a high humidity, there is another problem that a peeling is occurred. That is, when oxide such as SiO_2 , Ta_2O_5 , Al_2O_3 and the like and nitride such as Si_3N_4 , AlN and the like are used as a dielectric material, since such a dielectric material is less adhesive to a phase change type recording material, for example, under the high-temperature and high-humidity environment, the peeling and crack are occurred. Thereby, there is further problem that oxide such as SiO_2 , Ta_2O_5 , Al_2O_3 and the like and nitride such as Si_3N_4 , AlN and the like cannot be applied to a dielectric layer material.

A deterioration mechanism is summarized. In the first place, the more the times of repeating is increased, the more the above atom diffusion and chemical reaction are proceeded. Consequently, a composition in the recording layer is largely varied, thereby variations of the reflectance, the absorption and the like, and the variation of the recording characteristic (an amorphization sensitivity) and the erasure characteristic (a crystallization sensitivity and a crystallization rate) are actualized. It is supposed that in the protective layer, accompanied by the change of the optical characteristic, the composition changed, thereby such a change that a mechanical strength is reduced occurs. It can be considered a ZnS-SiO_2 film widely applied as an excellent protective layer has a high adhesiveness between the protective layer and the recording layer and this results from the atomic diffusion. Furthermore, it is also considered that such a protective layer substantially contains a limit of the repeating times.

Relating to a material containing Ag and S, that is, the elements which are easy to chemically react, the method of suppressing the reaction is disclosed in Japanese Patent Application Laid-open No. 5-217211. However, the following view is not disclosed in the above prior art. That is, relative to the phase change recording medium such as Ge-Sb-Te system, In-Sb-Te system and the like being developed for an application as the most possible material system, in order to enhance the cycle performance thereof, the layer comprising the material such as nitride, nitriding-oxide, etc. is formed between a dielectric protective layer and a phase change recording layer. The formed layer acts as a barrier layer for preventing an interdiffusion and the chemical reaction between the recording layer and the protective layer. Furthermore, more specifically, Ge-N or Ge-N-O is superior as the dielectric protective layer material which does not substantially have the above problem. This material has also an excellent performance as the barrier layer. This is not also disclosed in the prior art.

That is, a layer structure for realizing an excellent repeating characteristic and an excellent weather-proofness is not yet achieved. In order to solve the above problems, it is an object of the present invention to provide a medium structure for realizing a phase change optical recording medium having the excellent repeating characteristic and weather-proofness, the producing method thereof, and a method of recording and reproducing an information signal by using the recording medium.

SUMMARY OF THE INVENTION

In order to solve above problems, according to one aspect of the present invention, there is provided an optical

information recording medium comprising a recording layer generating a reversible phase change which can be optically detected according to an irradiation of an energy beam, and a material layer which is named a barrier layer formed in contact with at least one surface of the recording layer, wherein an atomic diffusion and a chemical reaction occurred between the protective layer and the recording layer are suppressed by the barrier layer.

5 A material constituting the barrier layer (a barrier material) itself can be applied to a protective layer material as it is. In this case, more specifically, it is expressed as the protective layer using the barrier material".

According to another aspect of the present invention, preferably, there is provided an optical information recording medium, wherein a barrier material layer is disposed at both sides of a recording layer.

10 According to a structure in which the barrier material is applied to a substrate side of the recording layer, an effect for suppressing the atomic diffusion and the chemical reaction between the recording layer and the protective layer is higher, thereby a cycle performance is enhanced. According to the structure in which the barrier material is applied to the side opposite to the substrate of the recording layer, the effect for enhancing a stability of rewrite performance is higher, thereby a reliability is enhanced. Not only the structure in which the barrier material is applied to both sides of the recording layer combines both characteristics, but also both performances are further enhanced.

15 According to further aspect of the present invention, preferably, there is provided an optical information recording medium, wherein when the barrier material is represented by M_aX_b (where, M denotes an aggregate of non-gas elements M_1, M_2, \dots , and X denotes the aggregate of gas elements X_1, X_2, \dots), regarding a ratio of a gas component $b/(a+b)$, the ratio of the barrier material layer at the substrate side is relatively higher than that of the barrier material layer at the side opposite to the substrate.

20 According to further aspect of the present invention, preferably, there is provided an optical information recording medium further comprising a metallic reflecting layer.

According to further aspect of the present invention, preferably, there is provided an optical information recording medium, wherein the protective layer using the barrier material" having a thin thickness of 60 nm or less is applied between the metallic reflecting layer and the recording layer for a quenching. Thereby, since the number of layers can be reduced, a preparing process can be simplified. Furthermore, since a cooling effect is enhanced, thereby a thermal interference between recording marks is reduced, an information signal can be densely recorded. That is, the structure is advantageous to a high density recording. More preferably, in this case, the barrier layer is also applied to the substrate side of the recording layer. Thereby, it is possible to obtain the medium which can realize a higher cycle performance and a higher density recording.

30 According to further aspect of the present invention, preferably, there is provided an optical information recording medium, wherein in the structure (a rather slow cooling structure) necessary for a dielectric layer having a thick thickness of 80 nm or more between the metallic reflecting layer of the recording layer and the recording layer, the barrier layer is applied to at least one side of the recording layer. Thereby, usually, in the rather slow cooling structure having a tendency of high heat-storing effect and a large thermal damage, the cycle performance can be largely enhanced.

35 According to further aspect of the present invention, there is provided an optical information recording medium, wherein the thickness of the barrier layer is at least more than 1 nm to 2 nm. Thereby, the above effect can be obtained. Preferably, the thickness is 5 nm or more. Thereby, even if a laser power used for recording is higher, the effect can be obtained. Furthermore, more preferably, the thickness is 20 nm or more. Thereby, a further effect can be obtained. Furthermore, more preferably, the thickness is 20 nm or more. Thereby, a higher reproducibility can be obtained in preparing.

40 According to further aspect of the present invention, there is provided an optical information recording medium, wherein the barrier material layer containing Ge-N or Ge-N-O is used as the barrier material.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein when Ge-N or Ge-N-O material layer is applied at both sides of the recording layer as the barrier layer or the protective layer, regarding a density of a gas element in Ge-N or Ge-N-O layer, that is, $(N+O)/(Ge+N+O)$, the density in Ge-N or Ge-N-O layer at the substrate side of the recording layer is relatively larger than that in Ge-N or Ge-N-O layer at the side opposite to the substrate of the recording layer.

45 According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein Ge-N composition region having a Ge density ranging from 35% to 90% is selected. More preferably, the range from 35% to 65% is selected.

50 According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein in case that the a Ge-N layer is applied to the substrate side of the recording layer (at the side which a laser beam is incident on), the Ge density ranging from 35% to 60% is selected. In case that the Ge-N layer is applied to the side opposite to the substrate of the recording layer, the Ge density ranging from 42.9% to 90% (preferably, 42.9% to 65%) is selected.

55 According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein in a triangular diagram in FIG. 5 showing three-element composition of Ge-N-O, Ge-N-O composition region is within a range surround by four composition points, B1 ($Ge_{90.0}, N_{10.0}$), B4 ($Ge_{83.4}, N_{3.3}, O_{13.3}$), G4 ($Ge_{31.1},$

$N_{13.8}$, $O_{55.1}$), $G1$ ($Ge_{0.35}$, $N_{0.65}$). In this region, there are such effects that the cycle performance is enhanced and an erasure performance is enhanced.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein in case that the Ge-N-O layer is applied to the substrate side of the recording layer (at the side which the laser beam is incident on), the region surrounded by four composition points D1 ($Ge_{60.0}$ $N_{40.0}$), D4 ($Ge_{48.8}$ $N_{10.2}$ $O_{41.0}$), G1 ($Ge_{35.0}$ $N_{65.0}$), G4 ($Ge_{31.1}$ $N_{13.8}$ $O_{55.1}$) is appropriate. In case that the Ge-N-O layer is applied to the side opposite to the substrate of the recording layer, the region surrounded by four composition points B1 ($Ge_{65.0}$ $N_{35.0}$), B4 ($Ge_{54.3}$ $N_{9.1}$ $O_{36.6}$), F1 ($Ge_{42.9}$ $N_{57.1}$), F4 ($Ge_{35.5}$ $N_{12.9}$ $O_{51.6}$) is appropriate. In this case, preferably, the region surrounded by four composition points C1 ($Ge_{65.0}$ $N_{35.0}$), C4 ($Ge_{53.9}$ $N_{9.2}$ $O_{36.9}$), F1 ($Ge_{42.9}$ $N_{57.1}$), F4 ($Ge_{35.5}$ $N_{12.9}$ $O_{51.6}$) is appropriate.

Similarly to the case of the Ge-N layer, when the Ge-N-O layer is formed at the side opposite to the substrate of the recording layer (at the side which the laser beam is not incident on), in a process of recording and erasing, there is less possibility that a Ge atom is included in the recording layer. The layer can be also applied to the composition region having a considerably high Ge density. On the contrary, when the Ge-N-O layer is formed at the substrate side of the recording layer (at the side which the laser beam is incident on), there is more possibility that the Ge atom is included in the recording layer. It is not preferable that the layer is applied to the composition region having a considerably high Ge density.

As described above, the Ge-N layer or the Ge-N-O layer is acted in such a manner that the atomic interdiffusion and chemical reaction generated between the recording layer and the protective layer usually comprising a dielectric material are suppressed. There is such an advantage that the Ge-N layer or the Ge-N-O layer has a higher adhesiveness to the recording layer, compared to other nitride films such as Si_3N_4 , AlN, etc. and a carbide film such as SiC, etc. The reason that the Ge-N layer or the Ge-N-O layer has a higher adhesiveness is as follows. Compared to other nitride films such as Si_3N_4 , AlN, etc., the Ge-N layer or the Ge-N-O layer enables to form the film with a relatively lower power at a high speed (for example, when a distance between a target and the substrate is 200 mm, if the target whose diameter is 100 mm is used, the film can be formed with 500W at 40 nm to 50 nm/minute). Accordingly, it is assumed that since an internal stress in the film is lower, the Ge-N layer or the Ge-N-O layer has a higher adhesiveness. However, this is not clear.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein a complex refractive index value $N+ik$ applies the Ge-N or Ge-N-O layer satisfying the range of $1.7 \leq n \leq 3.8$ and $0 \leq k \leq 0.8$. More preferably, when the barrier material layer is formed at the substrate side of the recording layer, the Ge-N or Ge-N-O layer satisfying the range of $1.7 \leq n \leq 2.8$ and $0 \leq k \leq 0.3$ is applied. When the barrier material layer is formed at the side opposite to the substrate, the Ge-N or Ge-N-O layer satisfying the range of $1.7 \leq n \leq 3.8$ and $0 \leq k \leq 0.8$ is applied. An optical constant is changed according to a ratio of O to N in the film, when O is less, the optical constant becomes larger. When O is more, the optical constant becomes smaller.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein a material thin film whose main component is Ge-Sb-Te is used as the recording layer.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein the material thin film whose main component is $ZnS-SiO_2$ is used as a dielectric protective layer material used together with the barrier layer.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein a material layer containing a main component comprising a nitride or a nitriding-oxide having at least one kind of element selected from the elements constituting the recording layer is used as the barrier material layer.

In general, although a nitride material is less adhesive to a chalcogenite material, the barrier layer containing nitride or nitriding-oxide being the element constituting the recording layer is used, thereby the elements in the barrier layer is common to the component element in the recording layer. Accordingly, the adhesiveness can be enhanced. In this case, it is possible to suppress the interdiffusion and the chemical reaction between the recording layer and the protective layer whose main component is the dielectric material. Thereby, the phase change optical recording medium having the excellent repeating performance excellent weatherproofness can be realized.

According to further aspect of the present invention, preferably there is provided an optical information recording medium, wherein at least one surface of the recording layer is nitrated or nitric-oxidized, thereby the barrier layer is formed.

In this case, since the recording layer and the nitride layer or the nitric-oxide layer have the films having a high continuity to each other, there is less problem relating to the adhesiveness. Accordingly, the optical information recording medium having the excellent repeating performance and the excellent weatherproofness can be obtained.

According to further aspect of the present invention, a method of preparing an optical information recording medium for solving the above problems, comprising a vacuum deposition method, DC sputtering method, a magnetron sputtering method, a laser sputtering method, an ion plating method, a CVD method and the like.

According to further aspect of the present invention, a method of preparing an optical information recording

medium, preferably, wherein a sputtering method is used, a single target comprising the main component M of the barrier material, a nitride target comprising M, a nitric-oxide target, or an oxide target is used in order that the barrier material layer is formed, so that a reactive sputtering is carried out in a mixed gas of a rare gas and the gas containing a nitride component or the mixed gas of the gas containing the rare gas and the nitride component and the gas containing an oxide component, thereby the barrier material layer is formed.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein Ar and Kr are used as the rare gas.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein N_2 is used as the gas containing the nitride component, and O_2 is used as the gas containing the oxide component.

When the barrier material layer is formed at either sides of the recording layer, an N_2 density in case that the barrier material layer is formed at the side opposite to the substrate of the recording layer is highly set than that in case that the barrier material layer is formed at the substrate side of the recording layer. Thereby, the structure having a further higher weather-proofness can be obtained.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein Ge is used as the main component M of the barrier material, a Ge target, a Ge-N target, a Ge-N-O target or a Ge-O target is used so that the reactive sputtering is carried out, thereby the barrier material layer is formed. More preferably, a Ge_3N_4 composition is used as the Ge-N target, a GeO composition is used as the Ge-O target, and Ge_3N_4 -GeO mixed target is used as the Ge-O-N target.

According to further aspect of the present invention, a method of preparing an optical information recording medium, more preferably, wherein Ge is used as the main component M of the barrier material, when the reactive sputtering is carried out, a total pressure of a sputter gas is more than 1 mTorr, and it is 50 mTorr or less. Within this range, a high sputter rate and a stable discharge can be obtained.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein Ge is used as the main component M of the barrier material, when the reactive sputtering is carried out, the sputter gas is the mixed gas containing at least Ar and N_2 , a partial pressure ratio of N_2 is ranging from 5% to 60%. Thereby, a better repeating performance and a better weather-proofness can be obtained. In this case, when the barrier layer is used at the substrate side of the recording layer, the partial pressure ratio of N_2 is ranging from 12% to 60% (preferably, 50% or less). Furthermore, when the barrier layer is used at the side opposite to the substrate, the partial pressure ratio of N_2 is ranging from 5% to 60% (preferably, 40% or less, more preferably, 33% or less).

Regarding the repeating performance, when a nitride partial pressure in the sputter gas is low, since much surplus Ge not combined to a nitrogen exists in the protective layer, the composition in the recording film is changed, accompanied with rewriting the signal, thereby a better characteristic cannot be obtained. Furthermore, when the nitrogen partial pressure in the sputter gas gets too high, much surplus nitrogen exists in the film, thereby similarly to the above case, the better repeating characteristic cannot be obtained.

Regarding the weather-proofness (adhesiveness), when the nitrogen partial pressure in the sputter gas is high and much surplus nitrogen exists in the film, after an acceleration test, a peeling is occurred. However, when the nitrogen partial pressure is low and the surplus Ge not combined to the nitrogen exists, the peeling is not occurred. It is assumed that since Ge contributes to a combination with the recording film, the peeling is not occurred.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein Ge is used as the main component M of the barrier material, when the reactive sputtering is carried out, the sputter gas is the mixed gas containing at least Ar and N_2 , a sputter power density is more than $1.27W/cm^2$, and a film forming rate is 18 nm/minute or more.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein Ge is used as the main component M of the barrier material, when the reactive sputtering is carried out, the sputter gas is the mixed gas containing at least Ar and N_2 , the film is formed in such a manner that the complex refractive index value $N+ik$ may satisfy the range $1.7 \leq n \leq 3.8$, $0 \leq k \leq 0.8$. More specifically, when the barrier material layer is formed at the substrate side of the recording layer, such a film forming condition as to satisfy the range $1.7 \leq n \leq 2.8$, $0 \leq k \leq 0.3$ is selected. When the barrier material layer is formed at the side opposite to the substrate, such a film forming condition as to satisfy the range $1.7 \leq n \leq 3.8$, $0 \leq k \leq 0.8$ is selected.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein at least one element among the materials constituting the recording layer is used as the main component of the barrier material layer, its single element target, its nitride target, its nitriding-oxide target or its oxide target is used, so that the reactive sputtering is carried out the mixed gas of the rare gas and the gas containing the nitrogen component or the mixed gas of the rare gas and the gas containing the nitrogen component and the gas containing the oxygen component, thereby the film is formed.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein the material itself constituting the recording layer is used as it is as the main component of

the barrier material layer, the target for forming the recording layer, its nitride target, its nitriding-oxide target, or its oxide target is used, so that the reactive sputtering is carried out the mixed gas of the rare gas and the gas containing the nitrogen component or the mixed gas of the rare gas and the gas containing the nitrogen component and the gas containing the oxygen component, thereby the film is formed.

According to further aspect of the present invention, a method of preparing an optical information recording medium, preferably, wherein the material itself constituting the recording layer is used as it is as the main component of the barrier material layer, in at least either a recording layer formation start time or a recording layer formation completion time, either a process of forming the recording layer in which the density of the gas containing the nitride component in the sputter gas is enhanced, or a process of forming the recording layer in which the densities of the gas containing the nitride component and the gas containing the oxide component are enhanced is used, thereby the recording layer formation can be achieved.

According to the above processes, a supply of the gas constituting the nitride component and the oxide component may be stopped when a recording layer portion is formed in the recording layer formation process.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a cross-sectional view showing a conventional structure of a phase change optical recording medium comprising four layers.

BEST MODE FOR EXECUTING THE INVENTION

30 An embodiment of an optical information recording medium according to the present invention is shown in FIG. 2. FIG. 2 shows the embodiment in case that a barrier layer is used at a substrate side of a recording layer.

According to the embodiment, a substrate 1 is a disc-shaped polycarbonate resin substrate having a thickness of 0.6 mm and a diameter of 120 mm. Since a polycarbonate has such merits as a low humidity, a low cost and the like, the polycarbonate is superior as a material used for the substrate. Aside from the polycarbonate resin, a glass, an
35 acrylic resin, a polyolefin resin, a vinyl chloride and the like can be also used. Although a metal can be also used, the medium must be designed in such a manner that a light is incident from the side where a film is formed. Any way, a kind of the substrate is not limited to the present invention.

A surface of the substrate is optically sufficiently flat. Furthermore, a spiral-shaped concave-convex groove track 7, for example, having a depth of 70 nm, a groove portion width of 0.74 μ m and a land portion width of 0.74 μ m is formed
40 all over the surface where a multi-layer film is formed. The concave-convex shape of the groove is operated as a guide, thereby a laser beam for recording and reproducing an information signal can be moved to an optional position. As a method of guiding the laser beam, a continuous servo method using the spiral-shaped groove or a concentrically formed groove and a sample servo method tracing a periodically arranged signal pit sequence are known. According to the method of guiding the laser beam, although the groove is appropriately formed on the substrate 1, this does not also
45 relate to a substance of the present invention.

According to the above embodiment, sequentially a protective layer 2 comprising a ZnS-SiO₂ (SiO₂ : 20 mol%) mixture layer, a barrier layer 8 containing Ge-N or Ge-N-O, a recording layer 3 comprising a Ge₂Sb_{2.3}Te₅ alloy thin film, a protective layer 4 comprising a ZnS-SiO₂ (SiO₂ : 20 mol%) mixture layer and a metallic reflecting layer 5 is formed on
50 a surface where the concave-convex groove track 7 of the substrate 1 is formed by a sputter method. An ultraviolet curing resin is used as an adhesive layer 9, thereby the same resin plate as the substrate 1 is laminated as a defense plate 10. When the barrier layer 8 is Ge-N, in an order from the protective layer 2 to the metallic reflecting layer 5, the thickness of each layer is sequentially 91 nm, 5 nm, 20 nm, 18 nm and 150 nm, respectively. When the barrier layer 8 is Ge-N-O, similarly, the thickness of each layer is sequentially 86 nm, 20 nm, 20 nm, 18 nm and 150 nm, respectively.

In general, the material forming the protective layers 2 and 4 is a dielectric material, which is sometimes called a
55 dielectric protective layer. Aside from ZnS-SiO₂, the materials which are conventionally used for the protective layer of the optical recording medium can be applied to the protective layer as it is. For example, an oxide layer comprising a single oxide or a compound oxide etc. such as Al, Mg, Si, Nb, Ta, Ti, Zr, Y, etc., a nitride layer comprising a nitride such as Al, B, Nb, Si, Ta, Ti, Zr, etc., a sulfide layer comprising a sulfide such as ZnS, PbS, etc., a selenide layer comprising

ZnSe, etc., a carbide layer comprising SiC, etc., a fluoride comprising CaF₂, LaF, etc., or a mixture of the above materials such as a material layer comprising ZnSe-SiO₂, Si-N-O, etc. can be used.

The material forming the recording layer 3 is a phase change material to be changed into a reversible state by receiving an irradiation of an energy beam such as a laser beam, etc.. More specifically, preferably, the material is reversibly changed between an amorphous state and a crystalline state by the irradiation of the laser light beam. Typically, a system containing Ge-Sb-Te, Ge-Te, In-Sb-Te, Sb-Te, Ge-Sb-Te-Pd, Ag-Sb-In-Te, Ge-Bi-Sb-Te, Ge-Bi-Te, Ge-Sn-Te, Ge-Sb-Te-Se, Ge-Bi-Te-Se, Ge-Te-Sn-Au, Ge-Sb-Te-Cr, In-Se, In-Se-Co and the like, or the system resulted from adding a gas admixture such as oxygen, nitrogen, etc. to these systems can be used.

When these thin films are formed, the thin films are in the amorphous state. When the films absorb an energy such as the laser beam, etc., the films are crystallized. If the films are practically used as the recording medium, the recording film being in the amorphous state when the film is formed is previously crystallized by using such a method as a laser beam irradiation, a flush light irradiation, or the like. The laser beam is thinly focused, and the crystallized recording film is irradiated with the focused light beam. Accordingly, the irradiated portion is amorphized, so that the optical constant is changed, thereby the record is carried out. By the above change, the changed portion where the above record is carried out is irradiated with such a weakened laser beam not as to further change the recording layer. A variation of a reflecting light strength or the variation of a transmitted light strength is detected, thereby the information is reproduced. When the information is rewritten, the laser light beam is irradiated, and the amorphous portion is re-crystallized, thereby a recording mark is erased. After the erasure, a new recording mark is formed. As described below, such an overwrite that an erasure operation and a recording operation are carried out during one rotation of the recording medium can be performed.

As described above, the material layer located between the protective layer 2 and the recording layer 3 as the barrier layer 8 is operated in such a manner that an atomic diffusion and a chemical reaction between the recording layer and the protective layer are prevented. Compared to the recording layer, the material layer is needed to comprise the material having a higher melting point and a higher density. Furthermore, it is necessary that the material layer comprises the material which is hard to react with the material constituting the recording layer and the dielectric protective layer and to generate the atomic diffusion. Moreover, it is necessary that the material layer comprises the material which is not peeled from any layers and further is hard to generate a crack, etc.. For example, the material provided with the above characteristic among the nitride, the oxide, the carbide, the nitriding-oxide, an carbide of oxygen, a carbide of nitrogen and the like is appropriate. Preferably, any material has slightly less oxygen and nitrogen than a stoichiometric compound composition. That is, for example, when a stoichiometric nitrogen compound composition of the element M and the nitriding-oxide are defined as M_aN_b, M_aN_b·M_cO_d (where, a, b, c and d denote a natural number), the composition of the material layer used for the barrier layer is required to be expressed as M_aN_{b1} (b1 < b) and M_aN_{b1}·M_cO_{d1} (b1 < b and d1 < d). More specifically, when the barrier layer is applied at the side opposite to the substrate of the recording layer, preferably, M_aN_{b2} (b2 < b) and M_aN_{b2}·M_cO_{d2} (b2 < b and d2 < d).

Accordingly, even in case of such a composition as Si-N, Al-N, Si-O-N, or the like, the composition is expressed as S_{i3}N_{m1} (m1 ≤ 4, preferably m1 < 4), AlN_{m2} (m2 ≤ 1, preferably m2 < 1), S_{i3}N_{m3}·S_iO_{m4} (m3 ≤ 4 and m4 < 2, preferably m3 < 4 and m4 ≤ 2, or m3 ≤ 4 and m4 < 2), thereby there is increased a possibility that the composition can be applied to the barrier layer.

Furthermore, when the barrier layer is formed at both the sides of the recording layer, an adhesiveness to the recording layer at the substrate side is different from that at the side opposite to the substrate. The substrate side of the recording layer has a relatively high adhesiveness, and the opposite side has a low adhesiveness. From an experimental result, when the barrier layer is formed at the substrate side of the recording layer, it is largely shifter from the stoichiometric composition. That is, when the barrier material is represented by M_aX_b (where, M denotes an aggregate of non-gas elements M₁, M₂, ... and X denotes the aggregate of gas elements X₁, X₂, ...), regarding a ratio of a gas component b/(a+b), the ratio of the barrier material layer at the substrate side is relatively higher than that of the barrier material layer at the side opposite to the substrate. Accordingly, the medium having an excellent weather-proofness can be constructed.

Here, typically, the example using Ge-N or Ge-N-O is shown.

A Ge-N layer or a Ge-N-O layer can only include at least Ge and N or Ge, N and O. The Ge-N layer or the Ge-N-O layer may also include other elements such as Ge-N-(O), Ge-Si-N-(O), Ge-Sb-N-(O), Ge-Cr-N-(O), Ge-Ti-N-(O), or the like. The other elements are, for example, Al, B, Ba, Bi, C, Ca, Ce, Cr, Dy, Eu, Ga, H, In, K, La, Mn, N, Nb, Ni, Pb, Pd, S, Si, Sb, Sn, Ta, Te, Ti, V, W, Yb, Zn, Zr, or the like.

Furthermore, as described below, the material forming the barrier layer may be replaced by the nitride and the nitriding-oxide of the material composing recording layer. For example, when the main component of the recording layer consists of three elements among Ag, In, Sb and Te, an interface layer can be Ag-N-(O), Sb-N-(O), In-N-(O), Te-N-(O) or a mixture of them such as Ag-Sb-N-(O). When the main component of the recording layer is Te-Si-Ge, Si-N-(O), Ge-N-(O), Te-N-(O) or the mixture of them may be, for example, Ge-Si-N-(O). Cr and Al are added to Ge-N and Ge-N-O, thereby the adhesiveness can be enhanced. More specifically, the addition of Cr enables to obtain a remarkable effect.

At an additive density of about 5% or more, the adhesiveness can be enhanced. A preparing condition which can form the barrier layer having an excellent adhesiveness is expanded. When the additive density exceeds 50%, the cycle performance tends to be reduced.

The reflecting layer 5 comprises the material having a high reflectance and a low corrosiveness. Instead of an Al-Cr alloy, a single Au, Al, Ag, Pd, Ni, Cr, Ta, Ti, Si, Co, etc. or the alloy whose base consists of them can be used. For example, Au-Cr, Au-Co, Al-Ta, Al-Ti, Ag-Cr, Au-Pd, and the like preferable.

According to the above explanation, as a position where the barrier layer is applied, such an example that the barrier layer is applied to the interface between the dielectric protective layer at the substrate side and the recording layer is shown. Aside from the example of FIG. 2, there are different variations shown in Figs. 3A to 3H and Figs. 4A to 4H as another example of FIG. 2. The shape of the groove, a contact layer and the defense plate shown in FIG. 2 are omitted. Although the structure of FIG. 3A is same as that of FIG. 2, for simplify by a comparison among FIG. 3A and Figs. 3B to 3H, FIG. 3A is again shown.

For example, when the barrier layer is used, even if not only the barrier layer is used at the substrate side of the recording layer as shown in FIG. 3A, but also the barrier layer is used at the reflecting layer side (shown in FIG. 3B) or at both sides (shown in FIG. 3C), a similar effect can be obtained.

Furthermore, even if this layer is applied all over a lower protective layer (shown in FIG. 3D), all over an upper protective layer (shown in FIG. 3E), or all over the lower and upper protective layers (shown in FIG. 3F) not as the barrier layer, but as the protective layer using the barrier material, the similar effect can be obtained. For example, in FIG. 3F, the total dielectric protective layers 2 and 4 at both sides of the recording layer 3 are formed by the material layer containing the barrier material, Ge-N or Ge-N-O. In this case, this material layer has a numeral 8.

Furthermore, according to such a structure that the barrier layer (where, a Ge-N layer or a Ge-N-O layer) is used at the substrate side of the recording layer 3 and the total protective layer 4 comprises the barrier material (where, the Ge-N layer or the Ge-N-O layer) at the side of the reflecting layer 5 (shown in FIG. 3G), the similar effect can be obtained. On the contrary, according to such a structure that the total protective layer 2 comprises the barrier material (where, the Ge-N layer or the Ge-N-O layer) at the substrate side and the barrier layer (where, the Ge-N layer or the Ge-N-O layer) is applied at the reflecting layer side (shown in FIG. 3H), the similar effect can be obtained.

The upper protective layer is thinned, thereby the structure is designed in such a manner that the distance between the recording layer and the metallic reflecting layer is reduced. This structure is called a quenching structure. According to the quenching structure, if two or more layers are formed at the upper side, since very thin layers must be deposited, two or more layers are not preferable in view of an accuracy administration of a film thickness, thereby it is difficult to prepare. In this case, the upper side comprises a single Ge-N layer or Ge-N-O layer, thereby there is generated such a merit that it is easy to prepare.

FIG. 4 shows the structure when the reflecting layer is removed from the structure in FIG. 3. Figs. 4A to 4H correspond to Figs. 3A to 3H. Furthermore, according to the structures shown in Figs. 3 and 4, in various views, such a structure that a semitransparent reflecting layer comprising Au and a semiconductor material (for example, Si, Ge or the alloy whose base is Si, Ge) is added to the substrate side (the side which the light is incident on) of the recording layer can be used (not shown).

Figs 3 and 4 show such a structure that an uppermost layer is provided with the overcoat layer 6. The overcoat layer 6 is only disposed in order to suppress an influence due to water, dusts and the like relative to the protective layer and the recording layer of the optical information recording medium. Accordingly, for example, such a structure that a dummy substrate is laminated, such a structure that two plates are laminated with the over coat layer surface faced to an inner side, or the like is appropriately used according to a usual method. Furthermore, although the drawing is omitted, in order to laminate plates, a hot melt adhesive and the adhesive of the ultraviolet curing resin or the like are applied.

In order that the cycle performance can be enhanced, more effectively, the barrier layer 8, that is, the Ge-N layer or the Ge-N-O layer is formed at the substrate 1 side of the recording layer 3. Since the laser beam is incident on the substrate side, a temperature at the substrate side tends to rise, thereby the composition change is easy to generate. Accordingly, it is assumed that the effect of the barrier layer becomes considerable.

Furthermore, in another view, when the barrier layer, that is, the Ge-N layer or the Ge-N-O layer is formed at the reflecting layer side of the recording layer, in addition to such a merit as to enhance the cycle performance, such a merit as to enhance the erasure performance can be obtained. This relates to the following phenomenon. That is, when the recording layer is irradiated with the laser beam so that the film is amorphized, in general, a solidification starts from the portion whose temperature is lower. That is, it is assumed that the structure of the recording film composition and the interface at the side (usually, the reflecting layer side) where a cooling starts is a principal factor for determining the condition of a generated amorphous solid. That is, it is assumed that the barrier layer enables to suppress the atomic diffusion from the protective layer to the recording layer, the recording film composition at the interface is also held by a cycle record, or the like.

Accordingly, since the substrate 1 comprises the material such as the metal in which the light cannot be transmit-

ted, when the light cannot be incident from the substrate side, note that this case is contrary to the above description. That is, in this case, in order that the cycle performance may be enhanced, effectively, the barrier layer, that is, the Ge-N layer or the Ge-N-O layer is formed at the side opposite to the substrate 1 of the recording layer 3. On the other hand, in order that the erasure performance may be enhanced, effectively, the barrier layer, that is, the Ge-N layer or the Ge-N-O layer is formed at the substrate 1 side of the recording layer 3. Any way, if the Ge-N layer or the Ge-N-O layer is formed at both sides of the recording layer, the above two merits can be simultaneously achieved.

Table 1 shows a layer structure corresponding to Figs. 3A to 3H and Figs. 4A to 4H. In the table, Sub denotes a substrate, DL denotes a protective layer, BL denotes a barrier layer (GeNO), AL denotes a recording layer, RL denotes a reflecting layer, and OC denotes an overcoat layer. Furthermore, in the protective layer, the layer applying the barrier material, that is, the Ge-N layer or the Ge-N-O layer is represented by DL(GeNO), and the layer not applying the barrier material layer is represented by only DL.

Next, as a typical barrier material, an appropriate composition range of the Ge-N layer or the Ge-N-O layer will be described below. FIG. 4(sic) is a triangular diagram showing the composition range of the Ge-N layer or the Ge-N-O layer applied to the present invention. In the appropriate composition of the Ge-N material which does not contain oxygen, the Ge density has a lowest limit value of 35% to 40%. If the lowest limit value is reduced to less than 35% to 40%, the adhesiveness to the recording layer is reduced. According to an acceleration environment test, a peeling phenomenon are exhibited.

Furthermore, the Ge density has a supremum value of about 90%. If the supremum value exceeds 90%, in a process of repeating recording and erasing, Ge is included in the recording film, thereby the cycle performance tends to be reduced. The appropriate Ge density in case that the Ge-N layer is formed at the substrate side of the recording layer is more or less different from that in case that the Ge-N layer is formed at side opposite to the substrate. The latter is little more highly set than the former, thereby the adhesiveness is higher.

For example, the appropriate region of the Ge density of the former is 35% to 60%, on one hand, the appropriate region of the latter is 40% to 90% (preferably, 40% to 65%). When the former and the latter are formed under the same condition, the appropriate Ge density is ranging from 40% to 60%. According to the present invention, since it is not necessary that both of them are formed under the same condition, the appropriate Ge density whose is within the range from 35% to 90% (preferably, from 35% to 65%) is the effective composition region. Within the range from 65% to 90%, the cycle performance tends to be relatively reduced.

Ge-N-O system containing oxygen is described below. An average composition ratio of Ge to N to O in the Ge-N-O protective layer is shown in the triangular diagram showing the three-element composition Ge-N-O in FIG. 5. The average composition ratio can be explained by using each composition point, that is, A1, B1 to B5, C1 to C5, D1 to D5, E1 to E5, F1 to F5, G1 to G5 and H1 to H3.

B2 (Ge89.7N9.8O0.5), B3 (Ge86.6N6.7O6.7), B4 (Ge83.4N3.3O13.3),
C2 (Ge64.4N33.8O1.8), C3 (Ge58.8N20.6O20.6), C4 (Ge53.9N9.2O36.9),
D2 (Ge59.5N38.5O2.0), D3 (Ge53.8N23.1O23.1), D4 (Ge48.8N10.2O41.0),
E2 (Ge49.6N47.9O2.5), E3 (Ge45.4N27.3O27.3), E4 (Ge42.3N11.5O46.2),
F2 (Ge42.4N54.7O2.9), F3 (Ge38.4N30.8O30.8), F4 (Ge35.5N12.9O51.6), and
G2 (Ge34.8N62.0O3.2), G3 (Ge32.6N33.7O33.7), G4 (Ge31.1N13.8O55.1) are defined as the composition points at which the following composition lines crosses one another. The composition lines are as follows:

a composition line B1-B5 connecting the composition point B1 (Ge90.0N10.0) to the composition point B5 (Ge80.0N20.0),

a composition line C1-C5 connecting the composition point C1 (Ge65.0N35.0) to the composition point C5 (Ge50.0N50.0),

a composition line D1-D5 connecting the composition point D1 (Ge60.0N40.0) to the composition point D5 (Ge45.0N55.0),

a composition line E1-E5 connecting the composition point E1 (Ge50.0N50.0) to the composition point E5 (Ge40.0N60.0),

a composition line F1-F5 connecting the composition point F1 (Ge42.9N57.1) to the composition point F5 (Ge33.3N66.7),

a composition line G1-G5 connecting the composition point G1 (Ge35.0N65.0) to the composition point G5 (Ge30.0N70.0),

a composition line A1-H2 connecting the composition point A1 (Ge100) to the composition point H2 (N95.0O5.0),

a composition line A1-H3 connecting the composition point A1 (Ge100) to the composition point H3 (N50.0O50.0), and

a composition line A1-H4 connecting the composition point A1 (Ge100) to the composition point H4 (N20.0O80.0).

That is, preferably the average composition ratio of Ge to N to O in the Ge-N-O layer is within the range surrounded by four composition points, that is, B1, B4, G4, G1 in the triangular diagram showing the three-element composition Ge-N-O shown in FIG. 5. Within this range, there are such an effect that the cycle performance and the erasure performance can be enhanced as described above.

Similarly to the case of the Ge-N layer, in case of the Ge-N-O layer, when the barrier layer is formed at the side opposite to the substrate of the recording layer (at the side which the laser beam is not incident on), in the process of recording and erasing, there is less possibility that the Ge atom is included in the recording layer. Accordingly, the layer can be applied to the composition region whose Ge density is considerably high. On the contrary, when the barrier layer is formed at the substrate side of the recording layer (at the side which the laser beam is incident on), there is more possibility that the Ge atom is included in the recording layer. Accordingly, it is not preferable that the layer is applied to the composition region whose Ge density is considerably high.

Accordingly, even within the composition region B1-B4-G4-G1, when the barrier layer is formed at the substrate side of the recording layer (at the side which the laser beam is incident on), the composition region surrounded by the four composition points, D1, D4, G4, G1 is preferable. When the barrier layer is formed at the side opposite to the substrate of the recording layer (at the side which the laser beam is not incident on), the composition region surrounded the four composition points B1, B4, F4, F1 (preferably, C1, C4, F4, F1) is more preferable.

When the Ge density exceeds the composition line B1-B4, there is more possibility that the Ge atom is included in the recording layer, thereby sometimes the characteristic of the recording layer is changed. On the contrary, when the Ge density is too less than the composition line G1-G4, gas-state oxygen and nitrogen included in the film are increased. Accordingly, for example, when a laser-heating is performed, the oxygen and nitrogen is outgassed relative to the interface to the recording layer, thereby sometimes there is occurred such a problem that the Ge-N-O protective layer is peeled from the recording layer, etc.. However, any way, if the Ge-N-O protective layer is formed at least one side of the recording layer, a predetermined effect can be obtained.

The component ratio of oxygen to nitrogen can be selected according to the optical constant (refractive index) when the structure of a recording device is determined. For example, in case of Ge_3N_4 - GeO_2 composition line, the closer a real part n and an imaginary part k of the complex refractive index $n+ik$ approach to the Ge_3N_4 side, the larger they become. The closer the real part n and the imaginary part k approach to the GeO_2 side, the smaller they become. Accordingly, when larger n , k are necessary, the composition containing much nitrogen can be selected. When smaller n , k are necessary, the composition containing much oxygen can be selected.

However, the higher the GeO_2 density becomes, the lower the melting point of the film becomes. When the melting point becomes too low, since a deformation is occurred due to the repeated laser irradiation, and the protective layer is mixed with the recording layer, an excessively low melting point is not preferable as the protective layer. Furthermore, since GeO_2 itself is subject to melt into water, when GeO_2 density becomes higher, there is such a problem that a moisture-proof of the protective layer is reduced.

In the composition region surrounded by the composition points B1, B4, G4, G1 (in addition to the composition points B1, B4, C1, C4, G4, G1, for example $\text{Ge}_{35}\text{N}_{30}\text{O}_{35}$, $\text{Ge}_{37}\text{N}_{18}\text{O}_{45}$, $\text{Ge}_{40}\text{N}_{55}\text{O}_{5}$), the good moisture-proof and cycle performance can be confirmed. In view of a repeating performance, in the region B1-B3-G3-G1 having a relatively less oxygen component (in addition to the composition points B1, B3, G3, G1, for example $\text{Ge}_{40}\text{N}_{40}\text{O}_{20}$, $\text{Ge}_{42}\text{N}_{53}\text{O}_{5}$, $\text{Ge}_{35}\text{N}_{35}\text{O}_{30}$), a good repeating performance can be confirmed.

In the composition whose oxygen density is low, for example, in the composition having a less oxygen component than the composition line A1-H2, the rigidity becomes little larger. Accordingly, compared to the composition having more oxygen component, the composition having less oxygen density has a little tendency to generate the crack and the peeling. However, a little oxygen is added to the composition having less oxygen density, thereby such an effect that the peeling and the crack are prevented can be obtained. As described below, even in the composition having less oxygen than the composition line A1-H2, if the thickness of the Ge-N-(O) layer is about 300 nm, there is no practical problem. Accordingly, this region can be applied.

When the Ge-N layer or the Ge-N-O layer is applied to the barrier layer, the film thickness thereof is needed to be at least 1 nm or more, preferably 2 nm or more, more preferably 5 nm or more. When the film thickness is less than 1 nm, such an effect that the diffusion is suppressed is reduced. Furthermore, the difference between 2 nm and 5 nm is an allowance relative to the power. Even if the thickness of 5 nm needs a higher power than 2 nm, such an effect that the cycle performance is enhanced can be obtained according to the diffusion and the chemical reaction. When the film thickness is 5 nm, a basic diffusion suppression effect can be sufficiently obtained. If the thickness is 20 nm or more, the above effect can be more reproducibly obtained.

When the Ge-N layer or the Ge-N-O layer is used as the protective layer, it is necessary that the thickness thereof is formed in such a manner that it is thicker than thickness of the layer used for the barrier layer. in case of a usual optical

disk, the film thickness of the dielectric protective layer can be only formed in order to have at most 300 nm. Accordingly, the thickness of about 300 nm is applied to the film thickness of the Ge-N protective layer or the Ge-N-O protective layer. In case of Ge-N layer or the Ge-N-O layer, there is no problem, and the crack and the like are not observed. Furthermore, in this point of view, there is such an advantage that the material system containing oxygen is not subject to crack. It is assumed that oxygen is included, thereby a structure flexibility is enhanced.

Next, a method of preparing the optical information recording medium will be explained. The multi-layer film constituting the recording medium according to the present invention can be formed by a gas phase deposition method such as a vacuum deposition method, DC sputtering method, a magnetron sputtering method, a laser sputtering method, an ion plating method, a CVD method and the like. Here, the example using the DC sputtering method and the magnetron sputtering method will be described.

FIG. 6 shows an embodiment of an apparatus for preparing the optical information recording medium. FIG. 6 shows a generally schematic structure. In the first place, a vacuum tank 11 of a sputter chamber is a positive electrode. The vacuum tank 11 is connected to a plus of a direct current power source 13 via a power source switch 12. Furthermore, the vacuum tank 11 is switching-connected to a matching circuit 15 connected to a high-frequency power source 14. Thereby, both of the DC sputtering using a direct current discharge and an RF sputtering using a high-frequency discharge can be carried out. The matching circuit 15 matches an impedance in the sputter chamber to the impedance at the power source.

A bottom portion of the vacuum tank 11 is provided with four negative electrodes 16, 17, 18, 19 (negative electrodes 18, 19 not shown) which also serve as a water cooler. An insulating material 44 is disposed around each negative electrode 16, 17, 18, 19, thereby the negative electrodes 16, 17, 18, 19 are insulated from the positive electrode. Furthermore, the negative electrodes 16, 17, 18, 19 can be grounded via switches 20, 21, 22, 23 (switches 22, 23 not shown).

A Ge-Sb-Te alloy target 45 bonded to a copper backing plate, a ZnS-SiO₂ (SiO₂ : 20 mol%) mixture target 46, an Al-Cr (Cr : 3 atoms%) alloy target 47 and a Ge target 48 are fixed to the negative electrodes 16, 17, 18, 19 via an O ring by a screw, respectively. Each target is disc-shaped, having a diameter of 100 mm and a thickness of 6 mm. Furthermore, a permanent magnet (not shown) is accommodated in the negative electrodes 16, 17, 18, 19, thereby a magnetron discharge can be carried out.

An air outlet 24 is disposed at a side surface the vacuum tank 11. A vacuum pump 26 is connected to the air outlet 24 via a pipe 25, thereby an exhaust can be carried out in such a manner that the sputter chamber is high vacuum. An upper portion of the vacuum tank 11 is provided with a rotating apparatus 27. A disk holder 29 is mounted to a rotary shaft 28 of the rotating apparatus 27. The substrate 1 is attached to the disk holder 29. A numeral 30 denotes a shutter. The shutter 30 is closed so that a pre-sputter is carried out. Furthermore, the shutter 30 is opened and closed, thereby a sputter start and a sputter completion are controlled.

One side of a gas pipe 31 for providing a sputter gas is connected to the vacuum tank 11. The other side of the gas pipe 31 is connected to an Ar gas cylinder 40, a Kr gas cylinder 41, an O₂ gas cylinder 42 and an N₂ gas cylinder 43 via a mass flow meters 32, 33, 34, 35 and valves 36, 37, 38, 39, respectively. Thereby, aside from the usual sputtering in an Ar gas atmosphere, the sputtering in a Kr gas atmosphere, a mixed gas of Ar gas, Kr gas and N₂ gas atmosphere (for example, Ar+N₂), a mixed gas of Ar gas, Kr gas, N₂ gas and O₂ gas atmosphere (for example, Ar+ N₂+O₂) can be carried out. The gas containing the nitrogen component is not limited to the N₂ gas, for example, ammonia, etc. is also included in the gas containing the nitrogen component. However, considering an apparatus contamination, etc., in general, the N₂ gas is preferable. When the Ge-N-O layer is formed, N₂O, NO, NO₂ or the like is used as the gas containing both of N and O, and the sputtering can be also carried out in the mixed gas of Ar and them.

The method of preparing the optical information recording medium having the structure shown in FIG. 3A as an embodiment of the optical information recording medium according to the present invention by using this apparatus will be described below. Here, simultaneously, such an example that the Ge-N layer or the Ge-N-O layer as the barrier layer is disposed at the substrate side of the recording layer will be explained (henceforth, in case of no particular explanation, an explanation is made in an order of Ge-N, Ge-N-O).

In the first place, the vacuum pump 26 is actuated, thereby the vacuum tank is exhausted to a high vacuum of 1×10^{-6} Torr or less. Next, a main valve is throttled, and at the same time, Ar gas is introduced into the vacuum tank, thereby a degree of vacuum reaches to 1 mTorr. The disk holder 29 is rotated, and the power source switch is turned on, thereby RF discharge is started by the ZnS-SiO₂ target 46 and the negative electrode 17. The pre-sputter is carried out with 500W power for five minutes, and after the discharge is stabilized, the shutter 30 is opened. After a ZnS-SiO₂ film having a predetermined thickness (according to the embodiment, as described above, 91 nm or 86 nm) is deposited on the substrate 1, the shutter 30 is closed. The protective layer 2 comprising the ZnS-SiO₂ film is formed on the substrate 1 provided with the groove track portion 7.

After the discharge is completed, once the main valve is entirely opened, the degree of vacuum is returned to 1×10^{-6} Torr. Thenceforth, the main valve is throttled again, the Ar gas and the N₂ gas are introduced at the ratio of 50% to 50%, thereby the total pressure is set to 20 mTorr. Next, the RF discharge is started by the Ge target 48 and the nega-

tive electrode 19. After five-minute pre-sputtering, the shutter 30 is opened, and the reactive sputter is carried out with 500W. The barrier layer 8 whose main component is Ge-N having a predetermined thickness (according to the embodiment, as described above, 5 nm or 20 nm) is formed on the previously formed ZnS-SiO₂ protective layer 2 (since the opening and closing operation of the shutter 30 and the valve operation are similar to the case of forming the following layers, the explanation is omitted). When the barrier layer whose main component is Ge-N-O is formed, in the above process, instead of introducing the Ar gas and the N₂ gas at the ratio of 50% to 50%, the Ar gas, the N₂ gas and the O₂ gas can be only introduced at the pressure ratio of 49.5% to 49.5% to 1%. Only this point is different from the above case. Similarly, the succeeding process is carried out.

Since Ge has more tendency to form the oxide rather than the nitride, for example, the O₂ density can be set considerably less than the N₂ density. In some cases, the mixed gas of the Ar gas and the gas containing an N component can be only used as an introducing gas, thereby the Ge-N film containing oxygen, that is, the Ge-N-O layer can be formed. In this case, such an administration that the degree of vacuum is set within a predetermined range before introducing the gas, etc. is carried out, thereby the O density in the Ge-N-O layer can be controlled in such a manner that a desired O density is obtained.

The composition of the Ge-N layer and the Ge-N-O layer can be identified by a combination of an auger electron spectral method (AES), a Ruthurford back scattering method (RBS), Inductive Combination high-frequency plasma spectral method (ICP), and the like. The compositions in this case are Ge44 N56, Ge40 N40 O20, respectively.

Next, DC discharge is started by the Ge-Sb-Te target 45 and the negative electrode 16, thereby the recording layer 3 is formed. The Ar gas is introduced so that the degree of vacuum is set to 0.5 mTorr. The sputtering is carried out with 100W power in such a manner that a predetermined film thickness (according to the embodiment, as described above, 20 nm) can be obtained. The formed recording layer 3 is in amorphous state.

Next, the ZnS-SiO₂ film of the upper protective layer 4 is formed under the same condition as the lower protective layer 2 of a first layer in such a manner that a predetermined film thickness (according to the embodiment, as described above, 18 nm) can be obtained. Finally, the Al-Cr target 47 is CD sputtered in the Ar gas atmosphere of 2 mTorr with 300W power. The Al-Cr alloy film of the metallic reflecting layer 5 is also deposited at a predetermined thickness (according to the embodiment, as described above, 150 nm), thereby the multi-layer film having a predetermined five-layer structure is formed on the substrate 1.

The formed medium is taken out the vacuum tank 11, and the metallic reflecting layer 5 is covered with the ultraviolet curing resin. The dummy substrate is laminated on the covered metallic reflecting layer 5 so carefully not as to generate a bubble. In this state, the ultraviolet is irradiated, and a coated layer of the ultraviolet curing resin is cured, thereby an adhesive structure provided with a contact layer 9 and a protective defense plate 10.

According to the above example, as the method of forming the Ge-N layer or the Ge-N-O layer, the metal Ge is used as the target, and the mixed gas of the Ar gas and the nitrogen gas or the mixed gas of the Ar gas, the nitrogen gas and the oxygen gas are used so that the film is formed by the reactive sputtering method. However, there are other methods.

Other methods are as follows. Instead of the metal Ge, a Ge-N compound (preferably, Ge₃N₄) is used as the target. The reactive sputtering is carried out in the mixed gas containing the rare gas and the nitrogen so that the film is prepared. Furthermore, a Ge-O compound (preferably, GeO, GeO₂) is used as the target. The reactive sputtering is carried out in the mixed gas of the rare gas and the nitrogen, or in the mixed gas of the rare gas, the nitrogen-containing gas and the oxygen-containing gas so that the film is prepared. Furthermore, a Ge-N-O compound (for example, the compound of Ge₃N₄ and GeO₂ or GeO) is used as the target. The reactive sputtering is carried out in the mixed gas of the rare gas and the nitrogen-containing gas, or in the mixed gas of the rare gas, the nitrogen-containing gas and the oxygen-containing gas so that the film is formed.

When the film is formed, in case that impurities such as Ar, H, Si, C, etc. contained in the sputter gas and the chamber are contained in the barrier layer 8, if the impurity density is 10 at % or less, the similar effect to the case that the impurity is not contained can be obtained. That is, preferably, the impurity density contained in the nitride and the oxide forming the barrier layer 8 is about 10 at % or less. In case of an admixture for positively enhancing the characteristic, the density is not limited to this range. For example, Cr can be added up to the same density as the Ge density at maximum, thereby Cr largely contributes to enhancing the adhesiveness to the recording layer, etc..

As a second method of forming the barrier layer, for example, the material of the recording layer is applied to the target, and the nitride and nitriding-oxide being the constituent elements of the recording layer are formed, thereby the barrier layer can be formed. For example, in case of a Ge-Sb-Te system recording layer, the Ge-Te-Sb alloy target is used so that Ge-Sb-Te-N and Ge-Sb-Te-N-O can be formed. In case of this method, for example, in the first place, after the protective layer is formed, the Ge-Sb-Te target is used, and the reactive sputtering is carried out in the mixed gas of Ar+N₂, thereby the Ge-Sb-Te-N film is formed in order to have a predetermined thickness. After then, Ar is used as the sputter gas, and the Ge-Sb-Te recording layer is formed. By this process, only one target is used, thereby the barrier layer and the recording layer can be formed.

According to the embodiment, such an example that the process of forming the recording layer is performed in inactive gas is shown. The nitrogen can be contained in the recording layer. In this case, the N₂ partial pressure is appro-

privately adjusted. In case of forming the recording layer, compared to the case of forming the barrier layer, a low N_2 density is selected, thereby the recording layer containing the nitrogen and the barrier layer can be laminated. Here, the example of preparing the optical information recording medium having the structure shown in FIG. 3A is shown. For example, as shown in FIG. 3F, in case of the structure having the protective layers comprising the barrier material at both sides of the recording layer 3, the protective layer comprising the nitride and nitriding-oxide, the recording layer and the protective layer comprising the nitride and nitriding-oxide can be formed according to the above process.

Furthermore, for example, as shown in FIG. 3E, when the protective layer comprising the barrier material is formed on only the upper surface of the recording layer 3, naturally, the films can be formed in the order of the recording layer, the protective layer comprising the nitride and nitriding-oxide. In case of this method, since the composition of the recording layer is common to that of the barrier layer or the protective layer, there is less fear that the chemical reaction and the interdiffusion are occurred. Accordingly, a higher adhesiveness can be easily obtained. Extending this view, for example, when the Ge-Sb-Te recording layer is used, it is advantageous that the constituent elements of the Ge-Sb-Te recording layer, that is, the nitride and nitriding-oxide such as Te and Sb are used as the barrier layer and the protective layer themselves. In this case, the metal Te and the metal Sb are used as the target, and Te-N, Te-N-O and Sb-N, Sb-N-O can be selectively independently formed, respectively. In any case, the effect corresponding to the Ge-N-O layer can be obtained. In case of the barrier layer and the protective layer using the nitride and the nitriding-oxide, for example, as shown by the case of Ge-N-O, the composition ration of the nitrogen element, the oxygen element and the metal element is not limited to the stoichiometric composition.

According to the present invention, when a heat is applied, in the constituent element of the recording layer and/or the constituent element of the dielectric material layer, a material movement is suppressed. The layer having a higher adhesiveness to the recording layer and/or the dielectric material layer is adhesively formed on at least one surface of the recording layer. If this requirement can be only satisfied, the constituent element of the recording layer is not limited to nitriding-oxide. Accordingly, even if the constituent element of the recording layer is a carbide or a fluoride, the constituent element can be applied. For example, the constituent element of the recording layer may be same as the constituent element (for example, Zn-N, Zn-N-O, etc.) of the dielectric protective layer. Furthermore, it is expected that the mixture of the compound except for nitriding-oxide can be applied. Even if In-Sb-Te and Ag-In-Sb-Te systems etc. which do not contain Ge are used as the recording material, the Ge-N film and the Ge-N-O film are effective.

Next, the formed recording medium is initialized. The initialization is carried out by the laser irradiation, as described below. Any other method, for example, the method using a flush exposure can be applied. Here, the disk medium is rotated at linear rate of 5m/s at uniform rate, and the laser beam having a wavelength of 780 nm is formed in such a manner that an oblong spot of $1\ \mu\text{m} \times 100\ \mu\text{m}$ (a half value width) is formed on the disk. The disk medium is located in such a manner that the longitudinal direction of the oblong spot thereof is a radius direction. The crystallization is sequentially carried out at a pitch of $30\ \mu\text{m}$ /rotation from an outer diameter to an inner diameter.

Thereby, the method of preparing the optical information recording medium according to one embodiment of the present invention is shown. If the number of layers and the layer thickness of the disk are changed, the above method is substantially similar. Furthermore, the medium having various structures as shown in Figs. 3A to 3H and Figs. 4A to 4H can be similarly formed.

Furthermore, a disk comprising a plurality of laminated recording layers in which a multi-layer recording can be carried out, and a disk comprising two laminated disks with rear surfaces thereof in which the record can be reproduced at both sides can be applied to the present invention.

Next, the signal is recorded on the optical information medium prepared by the above method, and the method of reproducing the record will be explained. In order to estimate the recording and reproducing characteristic, a deck is used. The deck is provided with a semiconductor laser light source whose wavelength is 680 nm, an optical head mounting an objective lens whose numerical aperture is 0.6, a linear motor for guiding the optical head to an optional position of the recording medium, a tracking servo mechanism for controlling a positioning, a circuit for the tracking servo mechanism, a focusing servo mechanism for controlling an attitude of the optical head and for irradiating a recording film surface with a laser spot, a circuit for the focusing servo mechanism, a laser drive circuit for modulating a power of the laser, a time interval analyzer for measuring a jitter value of the reproduced signal, and a rotation control mechanism for rotating the optical disk.

When the signal is recorded or overwritten, in the first place, the disk is rotated at a predetermined rate. The linear motor is operated so that the optical head is moved to the optional track position. Next, the focusing servo mechanism is operated so that the laser spot is focused on the recording film surface. Next, the tracking servo mechanism is operated so that the laser beam is tracked to an optional track. Next, the laser drive circuit is operated so that the power of the outputted laser is modulated corresponding to the information signal between an amorphizing pulse portion having a power level whose irradiation energy is relatively high and a crystallizing pulse portion having a power level whose irradiation energy is relatively low, as shown in FIG. 7. The optical information recording medium is irradiated with the laser beam, thereby such a state that an amorphous state and a crystalline state alternately exist is formed.

A peak pulse portion comprises a usually so-called multi-path formed by further narrow pulse sequence. After the

irradiated portion in the amorphizing pulse portion is melted in an instant, the portion is quenched, thereby the portion is in the amorphous state. the irradiated portion in the crystallizing pulse portion is annealed, thereby the portion is in the crystalline state.

Next, when the signal is reproduced, the irradiation power of the laser beam is set to a reproducing power level lower than the power level used for the crystallization in such a manner that the optical information recording medium is not further changed. The optically changed portion is irradiated with the laser beam, and a detector receives and detects a strength change generated corresponding to a difference between the amorphous state and the crystalline state of the reflecting light or the transmitted light.

A pulse waveform is not limited to the waveform shown in FIG. 7. For example, as shown in FIG. 8, (A) the amorphizing pulse is modulated between the amorphizing power level and the level less than the reproducing power level, (B) only pulse widths of a top pulse and a tail pulse are relatively longer than the pulse width of an intermediate pulse, (C) the amorphizing pulse width makes equal, (D) when the laser beam is amorphized, without a pulse modulation, the beam is irradiated, (E) such a period that the pulse has the power level less than the reproducing power level is necessarily provided before and/or after the amorphizing pulse, or the waveforms as shown in (A) to (E) are combined to one another, etc.. Thereby, various recording systems, reproducing systems and erasure systems can be applied.

A signal system is EFM, a shortest recording mark length is $0.61\text{ }\mu\text{m}$, and a shortest bit length is $0.41\text{ }\mu\text{m}$. The disk is fixed to a turn table, and it is rotated at 2045 rpm. At the position whose recording radius is 28 mm (linear rate 6m/s), the overwrite of a random signal for recording a mark length within the range from 3T to 11T on the groove track is repeated. The change of the signal amplitude and the jitter value (the ratio $(\sigma_{\text{sum}}/T_w)$ of σ_{sum} , that is, a sum of a standard deviation σ of the jitter value of each signal mark 3T-11T to a window width $T_w (= 34\text{ns})$, the jitter value can be only 12.8% or less) is examined.

For a comparison, three kinds of disks (A), (B), (C) are made on an experimental basis and estimated. The disks are as follows: (A) two disks comprising the structure according to the embodiment (a disk A1 is a Ge-N barrier layer disk, a disk A2 is a Ge-N-O barrier layer disk), (B) a disk comprising a conventional structure, that is, the structure of the disk (A) except for the Ge-N barrier layer or the Ge-N-O barrier layer, and (C) a disk comprising the conventional structure in which an Si_3N_4 interface layer is formed instead of the Ge-N barrier layer or the Ge-N-O barrier layer of the disk (A) according to the embodiment.

According to a first estimate item, after the record is repeated at 100,000 times, the jitter value (measured by such a method that the jitter between each mark front end and the jitter between each mark rear end are independently measured) is estimated. Such a case that both of the jitter between the mark front end and the front end and the jitter between the mark rear end and the rear end are less than a reference value and the jitter value is scarcely changed is represented by \odot . Such a case that although the jitter value is changed, the jitter value itself remains less than the reference value is represented by \circ . Such a case that after 100,000-time repeating, the jitter slightly exceeds the reference value is represented by \triangle . Such a case that after 10,000-time repeating, the jitter value already exceeds the reference value is represented by X. The power for estimate is set to a higher value by about 10% than a lowest limit jitter value, where the lowest limit jitter value denotes the value when an initial jitter value satisfies the value less than 12.8%.

According to a second estimate item, after 100,000-time repeating in the above experimental track, the amplitude value is observed, and the result is estimated. Such a case that less change is found is represented by \odot . Such a case that about 10% change is found is represented by \circ . Such a case that about 20% change is found is represented by \triangle . Such a case that the amplitude value is reduced to more than 20% is represented by X.

A third estimate item is a weather-proof. After the disks are left to stand under a high-temperature (90°C) and high-humidity (80%RH) environment for 200 hours and for 400 hours, the disks are examined with a microscope. Such a case that no change is found even after 400 hours is represented by \odot . Such a case that a slight peeling, etc. is found after 200 hours is represented by \circ . Such a case that a slight peeling is observed in 200 hours is represented by \triangle . Such a case that a large peeling is observed within 200 hours is represented by X.

The above experimental results are shown in a table 2. Thus, the structure according to the present invention is superior to the conventional structure in view of the repeating characteristic and the weather-proof.

Table 2

| Result 1 of comparing the characteristics of the optical disk applying the barrier layer according to the present invention to those of the prior art | | | |

| B | △ | △ | ⊙ |
| C | ○ | ○ | X |

Next, in order that the effect of the barrier layer relative to the erasure performance is confirmed, the result of a comparative test is shown. A disk (D) comprising the structure shown in FIG. 3B in which the barrier layer is used only at the reflecting layer side of the recording layer in the table 1, and a disk (E) comprising the structure shown in FIG. 3C in which the barrier layer is used at both sides of the recording layer are produced by the above method. The disks (D) and (E) are initialized. The composition of the reflecting layer and the recording layer is same as that of the disks (A) and (B).

The disks (D1) and (D2) comprises a laminated-layer structure, in which a ZnS-SiO₂ protective layer (86 nm), a Ge-Sb-Te recording layer (20 nm), a Ge-N or Ge-N-O barrier layer (5 nm), an ZnS-SiO₂ protective layer (18 nm) and an Al-Cr reflecting layer (150 nm) on the substrate. The disks (E1) and (E2) comprises a laminated-layer structure, in which a ZnS-SiO₂ protective layer (86 nm), a Ge-N or Ge-N-O barrier layer (5 nm), a Ge-Sb-Te recording layer (20 nm), a Ge-N or Ge-N-O barrier layer (5 nm), ZnS-SiO₂ protective layer (12 nm), and an Al-Cr reflecting layer (150 nm).

Here, when the Ge-N layer or the Ge-N-O layer is formed at the reflecting layer side of the recording layer, compared to the case that the Ge-N layer or the Ge-N-O layer is formed at the substrate side, the pressure ratio of the N₂ gas relative to Ar gas is reduced. The gas is introduced at the ratio of 80% Ar gas to 20% N₂ gas, or in the ratio of 80% Ar gas to 19.5% N₂ gas to 0.5% O₂ gas. The sputtering is carried out at the total pressure of 20 mTorr. As a result, the average composition of the Ge-N layer at the reflecting layer side is Ge65 N35, and the composition of the Ge-N-O layer at the reflecting layer side is Ge60 N30 O10.

The disks (A) to (E) are rotated at the linear rate 6m/s, and the result is recorded according to the above method. Here, a single signal having a 3T mark length is recorded. And after C/N ratio is measured, immediately the overwrite of a 11T signal is recorded. Thereby the 3T signal is erased, and a damping factor ratio (a degree of erasure) is measured. Next, after another signal is recorded, the disks are left to stand in a dryer at 90°, the overwrite of the 11T signal is recorded, and the degree of erasure is measured. The leaving time is two conditions, that is, 100 hours and 200 hours. The result is shown in a table 3.

In the table 3, ⊙ denotes that a sufficiently high erasure ratio more than 35dB is obtained. ○ denotes that the erasure ratio more than 30dB is obtained. △ denotes that the erasure ratio more than 26dB is obtained. X denotes that the erasure ratio is reduced to less than 26dB. Thereby, the Ge-N barrier layer or the Ge-N-O barrier layer is applied, thereby the erasure performance is enhanced. More specifically, when the barrier layer is formed at the reflecting layer side of the recording layer, a higher effect can be obtained.

Henceforth, according to more detailed experimental data, the present invention will be explained in detail. FIG. 9 schematically shows a film formation apparatus used for the following experiment. A vacuum pump (not shown) is connected to a vacuum container 49 through an air outlet 50 so that a high vacuum can be kept in the vacuum container 49. From a gas supplying opening 51, the Ar gas, the nitrogen gas, the oxygen gas or the mixed gas of them can be appropriately provided at a constant flow rate on demand. A numeral 52 denotes a substrate. The substrate 52 is mounted to a drive apparatus 53 for rotating the substrate 52. A numeral 54 denotes a sputter target. The sputter target 54 is connected to a negative electrode 55. Here, a disc-shaped material having a diameter of 10 cm and a thickness of 6 mm is used as the target. The negative electrode 55 is connected to a direct current power source or a high-frequency power source through a switch (not shown). Furthermore, the vacuum container 49 is grounded, thereby the vacuum container 49 and the substrate 52 are kept a positive electrode.

(Example 1)

The optical disks having the layer structure shown in Figs. 3A and 3B (a disk (1) and a disk (3) in a table 4) are made on an experimental basis. The recording layer 3 comprises a phase change material whose main component is a Ge₂Sb_{2.3}Te₅ alloy, and the dielectric protective layers 2 and 4 comprises a ZnS-SiO₂ film. When the film is formed, the gas is supplied in such a manner that each total pressure of the Ar gas becomes 1.0 mTorr and 0.5 mTorr, respectively, and each of the powers DC1.27 W/cm² and RF6.37 W/cm² is introduced into the negative electrode 55, respectively. Furthermore, when the reflecting layer (AlCr) 5 is formed, the Ar gas is supplied in such a manner that the total pressure becomes 3.0 mTorr, thereby the power DC 4.45W/cm² is introduced.

In the disk (1), after the dielectric protective layer is formed, sequentially, the barrier layer 8 is formed. In the disk (3), after the recording layer 3 is formed, sequentially, the barrier layer 8 is formed. In this case, Ge is used as the target, and the mixture of Ar and nitrogen is used as the sputter gas. Furthermore, the sputter gas pressure is 20 mTorr, the partial pressure ratio of Ar to nitrogen in the sputter gas is 2 : 1, and the sputter power is RF700W. Since the target is a disc whose diameter is 10 cm, converted into a sputter power density, the sputter power density is 6.37W/cm².

The film thickness of each layer is as follows: the disk (1) comprises the dielectric protective layer 2 having 86 nm, the barrier layer 8 having 5 nm, the recording layer 3 having 20 nm, the dielectric protective layer 4 having 17.7 nm and the reflecting layer 5 having 150 nm, and the disk (3) comprises the dielectric protective layer 2 having 91 nm, the recording layer 3 having 20 nm, the barrier layer 8 having 10 nm, the dielectric protective layer 4 having 15.2 nm and the reflecting layer 5 having 150 nm. As a comparative example, the conventional structure shown in Fig. 1 (a disk (0)) having no barrier layer is similarly produced, and it is compared to the disks (1) and (3). The disk (0) is provided with the dielectric protective layers 2 and 4 comprising the mixture of ZnS and SiO₂, and each layer film thickness is 91 nm and 17.7 nm, respectively. Furthermore, the recording layer 3 comprising a Ge₂Sb_{2.3}Te₅ alloy has the film thickness of 20 nm. The reflecting layer 5 comprising AlCr has the film thickness of 150 nm.

The repeating characteristic of the disks (1), (3), (0) is shown in a table 4. In the table 4, the repeating record characteristic is examined by the following method. That is, as described above, the EFM signal system is used. When the

shortest mark length becomes 0.61 μm , the marks 3T to 11T are recorded. The value resulted from dividing the jitter value between each front end and the jitter value between each rear end by the window width T (henceforth, referred to as the jitter value) is examined. As a result, the case that after 150,000-time repeating record, both of the jitter value between the front ends and the jitter value between the rear ends do not exceed 13% is represented by \odot . The case that after 150,000-time repeating, although at least either the jitter value between the front ends or the jitter value between the rear ends exceeds 13%, after 100,000-time repeating, both of them do not exceed 13% is represented by \circ . The case that after 100,000-time repeating, at least either the jitter value between the front ends or the jitter value between the rear ends exceeds 13% is represented by X. Thereby, in the disk provided with the barrier layer 8 having the structure according to the present invention, compared to the prior art, the repeating characteristic is enhanced.

(Example 2)

All the protective layers at the substrate side of the disk (1) in the table 4 in the example 1 are changed to the Ge-N layer or the Ge-N-O layer, thereby a disk (5) is formed (accordingly, the Ge-N protective layer or the Ge-N-O protective layer whose thickness is 91 nm is formed at the substrate side of the recording layer). Furthermore, all the protective layers at the reflecting layer side of the disk (3) in the table 4 are changed to the Ge-N layer or the Ge-N-O layer, thereby a disk (6) is formed (accordingly, the Ge-N protective layer or the Ge-N-O protective layer whose thickness is 25.2 nm is formed at the reflecting layer side of the recording layer). The repeating characteristic of disks (5) and (6) is examined by the same method as the example 1. Both of them can similarly obtain the result \odot . That is, the Ge-N layer or the Ge-N-O layer can be formed in such a manner that the Ge-N layer or the Ge-N-O layer can obtain a thickness necessary for the protective layer. Furthermore, even in this case, the excellent repeating performance can be obtained.

(Example 3)

Next, the recording layer 3 comprises a phase change material whose main component is a $\text{Ge}_2\text{Sb}_{2.3}\text{Te}_5$ alloy, when the barrier layer 8 is formed, Sb is used as the target, and the mixture of Ar and nitrogen is used as the sputter gas. On the above condition, the films comprising the structure shown in Figs. 3A and 3B are formed (a disk (2), a disk (4)). In this case, the film thickness of each layer is same as the thickness in the above case that Ge is used as the target. The sputter gas pressure of the barrier layer 8 is 20 mTorr, and the partial pressure ratio of Ar to nitrogen in the sputter gas is 3 to 1. In this case, the result of the repeating characteristic is shown in disk numbers (2) and (4) in the table 4.

According to the table 4, compared to the case that Ge is used as the target so that the film is formed, although the number of repeatable times is inferior, better repeating characteristic can be obtained than the comparative example.

Table 4

| Result 3 of comparing the characteristics of the optical disk applying the barrier layer according to the present invention to those of the prior art | | | |
|---|-----------------|-----------------------------|--------------------------|
| Disk Number | Layer Structure | Target of the Barrier Layer | Repeating Characteristic |

| (1) | FIG. 3A | Ge | \odot |
| (2) | FIG. 3A | Sb | \circ |
| (3) | FIG. 3B | Ge | \odot |
| (4) | FIG. 3B | Sb | \circ |

(Example 4)

Next, when the layer structure is constructed as shown in FIG. 3A, and Ge is used as the target for forming the barrier layer 8, the range of the film formation condition which can obtain a better characteristic is examined.

According to the embodiment, the total sputter gas pressure is constantly set to 20 mTorr, and the partial pressure ratio of Ar and nitrogen in the sputter gas has three kinds of ratio, that is, 2 : 1, 1 : 1 and 1 : 2. The sputter power of Ge is RF100W, 300W, 500W, 700W, 710W, 750W, 1 kW, 1.5 kW and 2 kW. That is, since the target is the disc whose diameter is 10 cm, when the sputter power is converted into the power density, the respective sputter powers are changed

to 1.27W/cm², 3.82W/cm², 6.37W/cm², 8.91W/cm², 9.04W/cm², 9.55 kW/cm², 12.7 kW/cm², 19.1 kW/cm² and 25.5 W/cm², respectively. Thereby, the film is formed, and the characteristic of the disks is examined. When the partial ratio of Ar and nitrogen is changed to 2 : 1, 1 : 1 and 1 : 2, respectively, the flow rate of nitrogen is constantly set to 50 sccm, and the flow rate of Ar is changed to 100 sccm, 50 sccm and 25 sccm corresponding to the flow rate of nitrogen 50 sccm. The main valve of the vacuum pump is throttled, thereby the sputter gas total pressure is set to 20 mTorr.

The layer structure is constructed similarly to the disks (1) and (2). The film thickness of each layer is as follows. The dielectric layer 2 is 86 nm, the barrier layer 8 is 5 nm, the recording layer 3 is 20 nm, the dielectric layer 4 is 17.7 nm and the reflecting layer 5 is 150 nm. The repeating characteristic is examined by the method shown in the example 1. The result is shown in a table 5. Furthermore, the adhesiveness is adopted as the estimate item of the weather-proof. The acceleration test is carried out at 90°C at 80%, a sampling is carried out in 100 hours, 150 hours and 200 hours, and the sample is observed with an optical microscope in order to find whether the peeling exists or not. The result is shown in a table 6A. In this case, the generated peeling is substantially ranging from 1 μm to 10 μm. ⊙ denotes the case that the sampling after 200 hours is not peeled at all. ○ denotes the case that although the sampling after 100 hours and 150 hours is not peeled, the sampling after 200 hours is peeled, even if slightly. △ denotes the case that although the sampling after 100 hours is not peeled, the sampling after 150 hours is peeled, even if slightly. X denotes the case that the sampling after 100 hours is peeled, even if slightly.

| Relationship between a condition of forming a film of a barrier layer applied to a substrate side of a recording layer and a weather-proof | | | |
|--|---|-------|-------|
| Sputter Power (W) | (Ar partial pressure) : (Nitrogen partial pressure) | | |
| | 2 : 1 | 1 : 1 | 1 : 2 |
| 100 | ○ | ○ | X |
| 300 | ○ | ○ | X |
| 500 | ○ | ○ | X |
| 700 | ⊙ | ○ | X |
| 710 | ⊙ | ⊙ | △ |
| 750 | ⊙ | ⊙ | ○ |
| 1000 | ⊙ | ⊙ | ○ |
| 1500 | ⊙ | ⊙ | ⊙ |
| 2000 | ⊙ | ⊙ | ⊙ |

Thereby, in view of the repeating characteristic, when the sputter power is more than RF300W, better characteristic can be obtained. In view of the adhesiveness, when the sputter power is more than RF100W, better good characteristic can be obtained. In either cases, the higher the sputter power becomes, the better the characteristic can be obtained. This reason is that the higher the sputter power becomes, the denser film can be formed.

Relating to the nitrogen partial pressure, in case of (Ar partial pressure) : (nitrogen partial pressure) = 1 : 2, better characteristic can be obtained only within the sputter power range more than 710W. when the nitrogen partial pressure is higher than an appropriate condition, since a surplus nitrogen not combined to Ge exists in the barrier layer, it is assumed that the peeling is generated due to the surplus nitrogen. On the same condition of the nitrogen partial pressure, when the sputter power is increased, there is reduced a possibility that the Ge atom sputtered on the target surface is combined to the nitrogen until the sputtered Ge atom is attached to the substrate surface. Thereby, since a mixture amount of the surplus nitrogen is reduced, it is expected that the region where better characteristic can be obtained exists.

As an analyzing result of the average composition ratio of the barrier layer 8 which can obtain better characteristic, in any case, the average composition ratio of Ge, O and N is within the range surrounded by four composition points shown the three-element composition diagram in FIG. 5, E1(Ge50.0N50.0), G1(Ge35.0N65.0), G4(Ge31.1N13.8O55.1), E4(Ge42.3N11.5O46.2).

In general, when Ge or Ge-N is used as the target and the mixed gas of the rare gas and nitrogen is provided so that the film is formed, there is a tendency that if the sputter power is relatively small, the Ge-N-O film containing a lot of oxygen is formed, and if the sputter power is relatively large, the Ge-N film whose oxygen-content is only an impurity level is formed.

As described above, preferably, the sputter power has the power density more than 1.27 Wcm^2 . When the power density is more than 3.82 Wcm^2 , better adhesiveness and recorded repeating characteristic can be obtained. In this case, a film formation rate is 18 nm/minute, when Ar partial pressure : nitrogen partial pressure = 1 : 1. Preferably, the film formation rate is more than 18 nm/minute.

(Example 5)

Next, the difference of the disk characteristic is examined according to the difference of the partial pressure ratio of the sputter gas pressure and the nitrogen partial pressure in the sputter gas. Thus, the layer structure comprises the same structure in Figs. 3A and 3E. Ge is used as the target, and the sputter power is constantly set to RF700W. when the total pressure of the sputter gas, Ar partial pressure and the nitrogen partial pressure are changed, the characteristic is examined. A FIG. 3A-type disk comprises a ZnS-SiO₂ protective layer whose film thickness is 86 nm, a Ge-N or Ge-N-O barrier layer whose film thickness is 5 nm, a Ge-Sb-Te recording layer whose film thickness is 20 nm, a ZnS-SiO₂ protective layer whose film thickness is 17.7 nm and an AlCr reflecting layer whose film thickness is 150 nm. A

FIG. 3E-type disk comprises a ZnS-SiO₂ protective layer whose film thickness is 91 nm, a Ge-Sb-Te recording layer whose film thickness is 20 nm, a Ge-N or Ge-N-O barrier layer whose film thickness is 17.7 nm, and an AlCr reflecting layer whose film thickness is 150 nm.

The repeating characteristic is estimated by the same method as the example 1 to 3. The weather-proof is estimated by the same method as the example 4. A table 6B shows the film formation condition and the estimate result. In the table 6B the disk (0) denotes the conventional disk in the example 1. Furthermore, marks are represented two by two, where the left mark and the right mark correspond to the result of the FIG. 3A-type disk and the result of the FIG. 3E-type disk, respectively.

Figs. 10 and 11, and Figs. 12 and 13 show respective cases of the repeating characteristic and the weatherproof. Here, the nitrogen partial pressure is represented by an abscissa axis, and Ar partial pressure is represented by an ordinate axis.

In the first place, in case of the 3A-type disk, as shown in FIG. 10, the film formation condition which can obtain better repeating characteristic is the case that the total pressure of the sputter gas exceeds 1 mTorr. Furthermore, when the total pressure is 10 mTorr, the nitrogen gas partial pressure in the sputter gas is ranging from 25% to 60%. Furthermore, when the total pressure is 20 mTorr, the nitrogen gas partial pressure in the sputter gas is ranging from 12% to 60%.

Furthermore, as shown in FIG. 12, the film formation condition which can obtain better weather-proof (adhesiveness) is the case that the total pressure of the sputter gas is more than 1 mTorr, similarly to the case of the repeating characteristic. In both cases of the total pressure 10 mTorr and the total pressure 20 mTorr, similarly, the nitrogen gas partial pressure in the sputter gas is within the range less than 60%, preferably less than 50%.

Next, in case of the 3E-type disk, as shown in FIG. 11, the film formation of the barrier layer condition which can obtain better repeating characteristic is the case that the total pressure of the sputter gas exceeds 1 mTorr. Furthermore, when the total pressure is 10 mTorr, the nitrogen gas partial pressure in the sputter gas is ranging from 15% to 60%. Furthermore, when the total pressure is 20 mTorr, the nitrogen gas partial pressure in the sputter gas is ranging from 5% to 60%. Furthermore, as shown in FIG. 13, the film formation condition which can obtain better weather-proof (adhesiveness) is the case that the total pressure of the sputter gas is more than 1 mTorr, similarly to the case of the repeating characteristic. In both cases of the total pressure 10 mTorr and the total pressure 20 mTorr, similarly, the nitrogen gas partial pressure in the sputter gas is within the range less than 40%, preferably less than 33%.

According to this analysis, the composition range of the Ge-N or Ge-N-O layer which can obtain better characteristic is examined. When this material layer is disposed at the substrate side of the recording layer, as shown in the triangular composition diagram shown in FIG. 5, the average composition ratio is within the region surrounded by four points, D1 (Ge60.0N40.0), D4(Ge48.8N10.2O41.0), G1(Ge35.0N65.0), G4(Ge31.1N13.8O55.1).

Furthermore, when the material layer is disposed at the side opposite to the substrate of the recording layer, the average composition ratio is within the range surrounded by four composition points, B1 (Ge90.0N10.0), B4(Ge83.4N3.3O13.3), F1(Ge42.9N57.1), F4(Ge35.5N12.9O51.6), more preferably, the composition range surrounded by four composition points, C1 (Ge65.0N35.0), C4(Ge53.9N9.2O36.9), F1(Ge42.9N57.1), F4(Ge35.5N12.9O51.6).

Regarding the repeating characteristic, when the nitrogen partial pressure in the sputter gas is low, since a lot of surplus Ge not connected to the nitrogen exists in the barrier layer. Accordingly, the composition of the recording layer is changed, accompanied by the rewrite of the signal. Thereby, better characteristic cannot be obtained. Since a temperature rise at the reflecting layer side of the recording layer is lower than that at the substrate side, a degree of the atom diffusion is relatively small, thereby the condition that the N₂ partial pressure is low can be used. On the contrary, when the nitrogen partial pressure in the sputter gas is too high, a lot of surplus nitrogen exists in the film. In this case, better repeating characteristic cannot be obtained.

Regarding the adhesiveness, when the nitrogen partial pressure in the sputter gas is high and a lot of surplus nitrogen exists in the film, the peeling is generated after the acceleration test. When the nitrogen partial pressure is low and the surplus Ge not combined to the nitrogen exists, the peeling is not generated. It is expected that the more Ge not combined to the nitrogen and oxygen exists, the higher an affinity for the recording layer component becomes.

As described above, in order to obtain the disk having better repeating characteristic of the record and the adhesiveness, the sputter gas condition (gas pressure, component ratio) is clear. When the sputter gas total pressure exceeds 50 mTorr, the film formation rate becomes small. Accordingly, it is not practical.

The film formation condition is the case that when the Ge-N or Ge-N-O layer is formed, the power density to be introduced into the target is 8.91W/cm². When the power to be introduced into the target is more than 8.91W/cm², a time until the Ge atom sputtered on the target surface is attached to the substrate surface becomes shorter than the above case, thereby nitriding and nitriding-oxidation are hardly generated. In this case, according to the rate, the nitrogen partial pressure in the sputter gas is appropriately increased, thereby the similar effect to the case that the power

density is 8.91 W/cm^2 can be obtained. On the contrary, when the introducing power is less than 8.91 W/cm^2 , since the nitriding and nitriding-oxidation are excessively generated, according to the rate, the nitrogen partial pressure can be only adjusted in such a manner that the nitrogen partial pressure of the sputter gas is appropriately reduced.

When the nitrogen partial pressure ratio in the sputter gas is more than about 90%, the sputtering is more or less unstable and it is not preferable. The value of the sputter power and the film formation rate is set to an optional value within the range in which the nitride or nitride-oxide can be formed. As described above, preferably, the sputter power density $> 1.27 \text{ W/cm}^2$, and the film formation rate $\geq 18 \text{ nm/minute}$.

(Example 6)

Next, when the film formation condition is changed, the change of the optical constant of the barrier layer is examined. In the first place, the sputter power of Ge is set to 700W, and the sputter total pressure is constantly set to 10 mTorr. When the nitrogen partial pressure ratio in the sputter gas is changed, that is, the change of the complex refractive index of the film on a line a in Figs. 10 and 11 is examined. The result is shown in FIG. 14. Furthermore, the sputter power is 700W, and the sputter total pressure is constantly set to 10 mTorr. When the nitrogen partial pressure ratio in the sputter gas is changed, that is, the change of the complex refractive index of the film on a line a' in Figs. 10 and 11 is examined. The result is shown in FIG. 15. Next, the partial pressure ratio of Ar and the nitrogen in the sputter gas is constantly set to 1 : 1, and the gas total pressure is changed. In this case, FIG. 16 shows the change of the optical constant of the film on a line b in Figs. 10 and 11.

These graphs are combined to the above application range of the nitrogen partial pressure. When the barrier layer is used at the substrate side of the recording layer, preferably, the complex refractive index value $n+ik$ of the barrier layer satisfies the range of $1.7 \leq n \leq 2.8$ and $0 \leq k \leq 0.3$. Furthermore, when the barrier layer is used at the side opposite to the substrate of the recording layer, preferably, the complex refractive index value $n+ik$ of the barrier layer satisfies the range of $1.7 \leq n \leq 3.8$ and $0 \leq k \leq 0.8$.

When the film composition is analyzed, if the film is formed by using the sputter total pressure 10 mTorr, the oxygen density is ranging about from 5% to 8%. In case of the sputter total pressure 20 mTorr, the oxygen density is ranging about from 10% to 20%, which is little more than the case of 10 mTorr.

In view of producing method, even if the film formation condition such as the sputter power, the sputter gas or the like is changed, the film is formed in such a manner that the complex refractive index of the Ge-N film or the Ge-O-N film satisfies the above range. Thereby, better characteristic can be obtained.

(Example 7)

Next, except that the structure comprises a barrier layers 8 whose film thickness are 10 nm, 20 nm, respectively, and a ZnS-SiO₂ protective layers 2 of the substrate side whose film thickness are 81 nm, 65.8 nm, respectively, a 2A-type disk having the same layer structure and the film thickness as the example 4 is produced. The film formation condition of the barrier layer 8 is as follows: the sputter power is RF700W, that is, the power density 8.91 W/cm^2 , the sputter gas total pressure is 20 mTorr, Ar partial pressure : the nitrogen partial pressure = 2 : 1, and the gas flow rate is similar to the above case.

As a result of examining the repeating characteristic and the weather-proof of the disk, similarly to the above case, a very good characteristic can be obtained.

(Example 8)

Next, the effect when the barrier layer is applied is shown by comparing the disks having different layer structure to one another. A table 7 shows the structure of the experimentally made disks and the estimate result of the cycle performance thereof. In the table 7, DL denotes the protective layer containing ZnS-SiO₂, AL denotes the recording layer containing Ge₂Sb₂.2Te₅, BL denotes the barrier layer containing Ge₅₀N₄₅O₅, and RL denotes the reflecting layer containing AlCr. More specifically, when the material is changed or the material is specified, the description such as DL(Ge-N-O) is included in ().

The estimate method is same as the case of the table 2. That is, the jitter value and the amplitude value are estimated. After 100,000-time repeating record, the jitter value (measured by such a method that the jitter between each mark front end and the jitter between each mark rear end are independently measured) is estimated. Such a case that both of the jitter between the mark front ends and the jitter between the mark rear ends are less than a reference value and the jitter value is scarcely changed is represented by ⊙. Such a case that although the jitter value is changed, the jitter value itself remains less than the reference value is represented by ○. Such a case that after 100,000-time repeating, the jitter slightly exceeds the reference value is represented by △. Such a case that after 10,000-time repeating, the jitter value already exceeds the reference value is represented by X. The estimate power is set to a higher value

by about 10% than the lowest limit jitter value, where the lowest limit jitter value denotes the value when an initial jitter value satisfies the value less than 12.8%. Furthermore, after 100,000-time repeating, the amplitude value is observed. Such a case that less change is found is represented by ⊙. Such a case that about 10% or less change is found is represented by ○. Such a case that about 20% change is found is represented by △. Such a case that the jitter value is reduced to more than 20% is represented by X. The table 7 shows the followings:

1) in case of no reflecting layer (a disk 41), the amplitude value is severely reduced, and the jitter value rise is large. However, the barrier layer is provided, thereby it is possible to obtain a considerable effect of the jitter performance and the amplitude performance (disks 42 and 43),

2) even if the reflecting layer is provided, when the reflecting layer is thin, or if the layer between the reflecting layer and the recording layer is thick (a disk 44 : in general, a so-called annealing structure), the same effect as the case that the reflecting layer is thick or the layer between the reflecting layer and the recording layer is thin (a disk 47 : in general, a so-called quenching structure) cannot be obtained,

3) if the barrier layer is applied to the annealing structure, a considerable effect can be obtained (disks 45 and 46),

4) in the quenching structure, the barrier layer is only disposed at one side of the recording layer, thereby the considerable effect can be obtained.

That is, in the structure having no reflecting layer or in the structure in which the protective layer having a thick thickness (for example, more than 80 nm) is formed between the recording layer and the reflecting layer, the barrier layer is considerably effective relative to the jitter value reduction and to the suppression of the amplitude reduction due to the repeating record. When many repeating times is necessary, the barrier layer is essential. Recently, in many cases, the above annealing structure can be applied to the optical disk overwriting at a high speed (for example, Noboru Yamada et al. Thermally balanced structure of phase-change optical disk for high speed and high density recording", Trans. Mat. Res. Soc. Jpn., Vol. 15B, 1035, (1993)). Accordingly, a combination of the annealing structure and barrier layer generates a large effect.

On the other hand, the structure having a thin protective layer (for example, 60 nm or less) formed between the recording layer and the reflecting layer is provided with the barrier layer as the protective layer. Thereby, more specifically, the amplitude performance can be enhanced. Accordingly, much more repeating times can be achieved.

Table 7 Effect comparison of the barrier layer relative to various layer structure

| Disk number | Disk layer structure | Repeating performance | |
|-------------|--|-----------------------|-----------|
| | | Jitter | Amplitude |
| 41 | DL 90 nm AL 22 nm DL 82 nm | × | × |
| 42 | DL 80 nm BL 10 nm AL 22 nm DL 82 nm | ○ | ○ |
| 43 | DL 80 nm BL 10 nm AL 22 nm BL 10 nm DL 72 nm | ⊙ | ⊙ |
| 44 | DL 90 nm AL 22 nm DL 80 nm RL(Au) 10 nm | △ | × |
| 45 | DL 80 nm BL 10 nm AL 22 nm DL 82 nm RL(Au) 10 nm | ○ | ○ |

| | | | | | | | |
|----|-------------|-------------|-------------|-------------------|---------------------|---|---|
| | 80 nm | 10 nm | 22 nm | 90 nm | u) 10 nm | | |
| 46 | DL 80 nm | BL 10 nm | AL 22 nm | DL(GeNO) 90 nm | RL(A u) 10 nm | ⊙ | ⊙ |
| 47 | DL 90 nm | | AL 22 nm | DL 60 nm | RL 150 nm | ○ | △ |
| 48 | DL 90 nm | BL 10 nm | AL 22 nm | DL 60 nm | RL 150 nm | ⊙ | ⊙ |
| 49 | DL 90 nm | | AL 22 nm | DL(GeNO) 60 nm | RL 150 nm | ⊙ | ⊙ |
| 50 | DL 90 nm | BL 10 nm | AL 22 nm | DL(GeNO) 60 nm | RL 150 nm | ⊙ | ⊙ |

30 (Example 9)

Whether or not the material layer except for the Ge-N, Ge-N-O layer can be used as the barrier layer is examined. As a material candidate, Si-N, Si-N-O, SiC, Sb-N-O, Zr-N-O, Ti-N, Al-N and Al-N-O are selected. In any case, the sputter condition is selected. Two kinds of compositions, that is, (A) a stoichiometric composition and (B) the composition containing about 5% more Si, Al, Ti, or the like than the stoichiometric composition are tested. The medium structure is a FIG. 3G-type structure. The barrier layer has the thickness of 10 nm. The medium structure comprises a ZnSe-SiO₂ protective layer whose thickness is 80 nm, the barrier layer, a Ge₂Sb_{2.5}Te₅ recording layer whose thickness is 20 nm, a barrier material layer whose thickness is 20 nm, and an Au reflecting layer whose thickness is 50 nm deposited on a polycarbide substrate whose thickness is 1.2 mm by the sputtering method. After overcoating, a hot melt adhesive is used so that a defense plate is laminated. Next an initial crystallization is carried out by the laser method. Furthermore, for a comparison, the structure in which the barrier layer is not used is also prepared. These disks are rotated at a linear rate of 3.5m/s, and an EFM signal (random signal) having the 3T mark whose length is 0.6 μm is repeatedly overwritten, and the cycle performance is estimated. Furthermore, these disks are left to stand under the acceleration condition of 90°C and 80%RH for 100 hours, and the state of the disks is estimated.

The result is shown in a table 8. In the table 8, regarding the cycle performance, ○ means that after 100,000-repeating, the effect is obtained. That is, there is such an advancement that the jitter value rise and the amplitude value reduction are clearly less than the reference value. △ means that a little effect is obtained. X means that no effect is obtained. Furthermore, regarding the weather-proof, ○ means that no change is detected. X means that such a change as the peeling, etc. is detected. △ means that a little change such as the peeling, etc. is detected. Thus, regarding the cycle performance, there is a tendency that both of groups (A) and (B) are improved. Regarding the weather-proof, the group (B) is sprier to the group (A), that is, there is more possibility that the composition containing little less N, O or the like than the stoichiometric composition can be applied to the barrier layer.

Table 8

| Comparison of barrier materials | | | | | |
|---------------------------------|----------------------|-------|--------------|-------|--------------|
| | Material composition | A | | B | |
| | | Cycle | Weatherproof | Cycle | Weatherproof |
| 51 | Si - N | △ | X | △ | △ |
| 52 | Si - N - O | △ | X | ○ | ○ |
| 53 | SiC | △ | X | ○ | △ |
| 54 | Sb - N | △ | X | △ | ○ |
| 55 | Sb - N - O | △ | X | △ | ○ |
| 56 | Zr - N | △ | X | ○ | ○ |
| 57 | Zr - N - O | △ | X | ○ | ○ |
| 58 | Ti - N | △ | X | ○ | △ |
| 59 | Al - N | △ | X | ○ | △ |
| 60 | Al - N - O | △ | X | ○ | ○ |

As described above, according to the present invention, it is possible to provide the optical information recording medium in which the change of the recording characteristic and the reproducing characteristic due to repeating the record and reproduction is lower and further the weather-proof is excellent, the producing method thereof and a method of recording and reproducing the information.

Claims

1. An optical information recording medium comprising

a barrier layer comprising a barrier material,
a protective layer disposed at one side of said barrier layer; and

a recording layer generating a reversible phase-change which can be optically detected according to an irradiation of an energy beam, said recording layer being disposed at the other side of said barrier layer; and wherein
said barrier layer suppresses a diffusion of at least either an element of said recording layer or an element of said protective layer, and/or said barrier layer suppresses a chemical reaction between an element of said recording layer and an element of said protective layer.

2. An optical information recording medium according to claim 1, wherein said protective layer contains barrier material as a main component.
3. An optical information recording medium according to claim 1, wherein said either protective layer consists of barrier material.
4. An optical information recording medium according to claim 1, 2, or 3, wherein said recording layer is between protective layers containing barrier material, between said barrier layer, or between said barrier layer and protective layer containing barrier material and when said barrier material is represented by M_aX_b (where, M denotes a single non-gas element or a compound of a plurality of different non-gas elements, and X denotes a single gas element or a compound of a plurality of different gas elements), a value $b/(a+b)$ of the barrier material of said recording layer existing at the energy beam-incident side is larger than that of the barrier material existing at the side opposite to the energy beam-incident side.
5. An optical information recording medium according to claim 1, wherein a reflecting layer is disposed at the side of said recording layer opposite to the energy beam-incident side.

6. An optical information recording medium according to claim 5, wherein protective layer is disposed between said reflecting layer and said recording layer and said protective layer whose main component is barrier material has a thickness of 60 nm or less.
- 5 7. An optical information recording medium according to claim 6, wherein barrier layer is disposed at the energy beam-incident side surface of said recording layer.
8. An optical information recording medium according to claim 5, wherein protective layer disposed between said recording layer and said reflecting layer has the thickness of 80 nm or more.
- 10 9. An optical information recording medium according to any one of claims 1 to 8, wherein thickness of said protective layer is 1 nm or more.
- 15 10. An optical information recording medium according to claim 1,2,or 3, wherein the barrier material is either a nitride of the non-gas element or a oxynitride of the non-gas element.
11. An optical information recording medium according to claim 4, wherein the barrier material is either a nitride of the non-gas element or a oxynitride of the non-gas element.
- 20 12. An optical information recording medium according to claim 10, wherein the barrier material is such material that amount of at least nitrogen or oxygen is less than a stoichiometric composition.
13. An optical information recording medium according to claim 11, wherein the barrier material is such material that amount of at least nitrogen or oxygen is less than a stoichiometric composition.
- 25 14. An optical information recording medium according to claim 10, said gas element is any one of Ge, Sb, Si, Zr, Ti or Al.
- 15 15. An optical information recording medium according to claim 11, said gas element is any one of Ge, Sb, Si, Zr, Ti or Al.
16. An optical information recording medium according to claim 1 or 2, wherein said barrier material contains Ge-N or Ge-N-O.
- 35 17. An optical information recording medium according to claim 16, wherein the barrier material is such material that amount of at least nitrogen or oxygen is less than a stoichiometric composition.
18. An optical information recording medium according to claim 1 ,2,3,4,10,12,or 16 wherein said barrier material contains at least one element of Cr or Al as additive.
- 40 19. An optical information recording medium according to claim 18, wherein a density of said at least one element of Cr or Al is equal to or less than the density of said non-gas element component in said barrier material.
- 45 20. An optical information recording medium according to claim 16, wherein such layer containing barrier material is formed on the surfaces at both sides of said recording layer, and a Ge density in said barrier material at the energy beam-incident side is equal or less than the Ge density in said barrier material at the side opposite to the energy beam-incident side.
- 50 21. An optical information recording medium according to claim 16, wherein the barrier material is Ge and the Ge density in said barrier material is ranging from 35% to 90%.
22. An optical information recording medium according to claim 21, wherein the Ge density in said barrier material at the energy beam-incident side of said recording layer is ranging from 35% to 60%.
- 55 23. An optical information recording medium according to claim 21, wherein the Ge density in said barrier material at the side opposite to the energy beam-incident side of said recording layer is ranging from 40% to 90%
24. An optical information recording medium according to claim 21, wherein the Ge density in said barrier material at

the side opposite to the energy beam-incident side of said recording layer is ranging from 40% to 65%

25. An optical information recording medium according to claim 16, wherein the composition of said barrier material is one composition existing within a region surrounded by four composition points B1 (Ge_{90.0}, N_{10.0}), B4 (Ge_{83.4}, N_{3.3}, O_{13.3}), G1 (Ge_{35.0}, N_{65.0}), G4 (Ge_{31.1}, N_{13.8}, O_{55.1}) in a three-element composition diagram whose vertices are Ge, N, O.

26. An optical information recording medium according to claim 25, wherein composition of said barrier material at the energy beam-incident side of said recording layer is one composition existing within the region surrounded by four composition points D1 (Ge_{60.0}, N_{40.0}), D4 (Ge_{48.8}, N_{10.2}, O_{41.0}), G1 (Ge_{35.0}, N_{65.0}), G4 (Ge_{31.1}, N_{13.8}, O_{55.1}) in the three-element composition diagram whose vertices are Ge, N, O.

27. An optical information recording medium according to claim 25, wherein composition of said barrier material at side opposite to the energy beam-incident side of said recording layer is one composition existing within the region surrounded by four composition points B1 (Ge_{65.0}, N_{35.0}), B4 (Ge_{53.9}, N_{9.2}, O_{36.9}), F1 (Ge_{42.9}, N_{57.1}), F4 (Ge_{35.5}, N_{12.9}, O_{51.6}) in the three-element composition diagram whose vertices are Ge, N, O.

28. An optical information recording medium according to claim 27, wherein composition of said barrier material at side opposite to the energy beam-incident side of said recording layer is one composition existing within the region surrounded by four composition points C1 (Ge_{65.0}, N_{35.0}), C4 (Ge_{53.9}, N_{9.2}, O_{36.9}), F1 (Ge_{42.9}, N_{57.1}), F4 (Ge_{35.5}, N_{12.9}, O_{51.6}) in the three-element composition diagram whose vertices are Ge, N, O.

29. An optical information recording medium according to claim 1,2,3,or,16, wherein a value n and a value k included in a complex refractive index $n+ik$ of said barrier material are within the range of $1.7 \leq n \leq 3.8$ and $0 \leq k \leq 0.8$, respectively.

30. An optical information recording medium according to claim 29, wherein the value n and the value k included in the complex refractive index $n+ik$ of said barrier material are within the range of $1.7 \leq n \leq 2.8$ and $0 \leq k \leq 0.3$, respectively.

31. An optical information recording medium according to claim 1 or 2, wherein a structure material of said recording layer is a phase-change material whose base is Te, Sb or Se.

32. An optical information recording medium according to claim 31, wherein said phase-change material contains Ge-Sb-Te.

33. An optical information recording medium according to claim 1, wherein material of said protective layer and said material is an optically transparent dielectric material, containing at least one element selected from such group of O, S and Se.

34. An optical information recording medium according to claim 1,2,or 3 wherein said barrier material contains either the nitride or oxynitride of at least one kind of element selected from such elements constituting said recording layer.

35. An optical information recording medium according to claim 1,or 2 wherein said barrier material is a nitride of at least an element composing said recording layer or oxynitride of at least an element composing said recording layer.

36. A method of producing an optical information recording medium comprising steps of a first step of forming a protective layer or a barrier layer on a base substrate, a second step of forming on the protective or barrier layer, a recording layer generating a reversible phase-change which can be optically detected according to an irradiation of an energy beam, or a barrier layer, and a third step of forming on the recording layer or the barrier layer of the second step, a protective layer, a recording layer or barrier layer, wherein said barrier layer or barrier layers are formed by a high-frequency sputtering method in an atmosphere containing at least rare gas by using such target containing barrier material as main component.

37. A method of producing an optical information recording medium according to claim 36, wherein a process of forming protective layer disposed at at least one side of said recording layer, includes such process of forming the pro-

protective layer by a high-frequency sputtering method in an atmosphere containing at least rare gas by using such target containing barrier material as main component.

38. A method of producing an optical information recording medium according to claim 37, wherein the target is made by barrier material.
39. A method of producing an optical information recording medium according to claim 36 or 37, wherein said target is at least one kind selected from such group of single target of non-gas component of the barrier material, a nitride target of the non-gas component, a oxynitride target of the non-gas component, and an oxide target of the non-gas component.
40. A method of producing an optical information recording medium according to claim 36 or 37, wherein forming process of the barrier layer or forming process of the protective layer containing said barrier material is such process that a reactive sputtering is executed in atmosphere containing a mixed gas, and said mixed gas contains at least rare gas and gas containing nitrogen component or said mixed gas contains at least rare gas, gas containing nitrogen component and gas containing an oxygen component.
41. A method of producing an optical information recording medium according to claim 36, wherein said rare gas contains at least Ar and/or Kr.
42. A method of producing an optical information recording medium according to claim 36 or 37, wherein in the process of forming at both sides of said recording layer said barrier layer or protective layer containing barrier material, a nitrogen partial pressure in a sputter atmosphere gas when such layer at the energy beam-incident side is formed is higher than a nitrogen partial pressure in a sputter atmosphere gas when such layer at the side opposite to the energy beam-incident side is formed.
43. A method of producing an optical information recording medium according to claim 36, wherein a non-gas component of said barrier material is Ge, and said barrier layer or said protective layer is formed by using a reactive sputtering method where said barrier material is used as a target.
44. A method of producing an optical information recording medium according to claim 43, wherein the material of said target is at least one selected from such group of a Ge_3N_4 compound, a GeO compound, a GeO_2 compound, a Ge_3N_4 -GeO mixture, or a Ge_3N_4 - GeO_2 mixture.
45. A method of producing an optical information recording medium according to claim 43, wherein said reactive sputtering is carried out in the atmosphere gas whose total pressure is ranging 1 mTorr to 50 mTorr.
46. A method of producing an optical information recording medium according to claim 43, wherein the atmosphere gas of said reactive sputtering is a mixed gas containing at least rare gas and N_2 , and a partial pressure ratio of the N_2 is more than 10% and less than 66%.
47. A method of producing an optical information recording medium according to claim 46, wherein said partial pressure ratio of N_2 is more than 10% and less than 50%.
48. A method of producing an optical information recording medium according to claim 43, wherein a power density of said reactive sputtering is higher than 1.27 Wcm^{-2} , and the sputter atmosphere contains a mixed gas of at least rare gas and N_2 .
49. A method of producing an optical information recording medium according to claim 45, wherein a sputter rate of said reactive sputtering is more than 18 nm/minute.
50. A method of producing an optical information recording medium according to claim 43, wherein a complex refractive index value $n+ik$ of said barrier layer or said protective layer is within the range of $1.7 \leq n \leq 3.8$ and $0 \leq k \leq 0.8$.
51. A method of producing an optical information recording medium according to claim 36 or 37, wherein said target is a single target of one element among elements constituting said recording layer, a target of compound of said elements constituting said recording layer, a target of a nitride of said element, a target of an oxynitride of said element, or a target of an oxide of said element, and the sputter atmosphere gas is such mixed gas of rare gas and

gas containing nitrogen component, or such mixed gas of rare gas and gas containing nitrogen component and gas containing oxygen component.

52. A method of producing an optical information recording medium according to claim 36 or 37, wherein said target is a target of material for forming said recording layer, a target of a nitride of material for forming said recording layer, a target of an oxynitride of material for forming said recording layer, or a target of an oxide of material for forming said recording layer, and the sputter atmosphere gas is such mixed gas of rare gas and gas containing nitrogen component, or such mixed gas of rare gas and gas containing nitrogen component and gas containing oxygen component.

53. A method of producing an optical information recording medium according to claim 36 or 37, wherein material of the target used for forming said barrier layer or protective layer containing said barrier material is same as that of the target used for forming said recording layer, and at such time of starting and/or completing of said forming of said recording layer, a partial pressure of gas containing nitrogen component in the sputtering atmosphere gas is increased, or a partial pressure of gas containing oxygen component in the sputtering atmosphere is increased.

54. A method of recording/erasing/reproducing an optical information wherein recording, reproducing and erasing information on the optical information recording medium according to claim 1 by irradiating laser beam with controlling power of the laser beam.

55. A method of recording/erasing/reproducing an optical information, wherein an optical information recording medium provided with a recording layer generating a reversible phase-change which can be optically detected according to an irradiation of an energy beam, a barrier layer and a protective layer on a substrate is used,

when a signal is recorded and overwritten to said recording layer, an irradiation power of said laser beam is modulated between an amorphization power level having a relatively larger irradiation energy and a crystallization power level having relatively less irradiation energy according to an information signal, and said recording layer is irradiated with the modulated laser beam, and an amorphous state portion and crystalline state portion are selectively formed;

when the signal of said recording layer is erased, the irradiation power of said laser beam is set to said crystallization power level which changes said recording layer into the crystalline state;

when the signal of said recording layer is reproduced, the irradiation power of said laser beam is irradiated to said recording layer with the power level less than said crystallization power level and with a reproducing power level in such a manner that at least said recording layer is not changed, and by utilizing an optical characteristic difference according to a phase change between the amorphous state and the crystalline state, a light strength of a reflecting light or a transmitted light from said recording layer is detected, thereby a state of said recording layer is detected;

wherein said barrier layer of said optical information recording medium has such barrier material that can suppress diffusion of either an element of said recording layer or an element of said protective layer, and/or can suppress chemical reaction of any element of said recording layer and any element of said protective layer, and said barrier layer is formed between either side of said recording layer and said protective layer, or formed between each of both sides of said recording layer and said protective layers.

56. A method of recording/erasing/reproducing an optical information according to claim 55, wherein material of said protective layer of said optical information recording medium has barrier material as a main component.

57. A method of recording/erasing/reproducing an optical information according to claim 55, or 56 wherein said barrier material contains Ge-N or Ge-N-O.

International application No.

PCT/JP97/00729

| A. CLASSIFICATION OF SUBJECT MATTER | | |
|--|---|--|
| Int. Cl ⁶ G11B7/24, 7/26, 7/00 | | |
| According to International Patent Classification (IPC) or to both national classification and IPC | | |
| B. FIELDS SEARCHED | | |
| Minimum documentation searched (classification system followed by classification symbols) | | |
| Int. Cl ⁶ G11B7/24, 7/26, 7/00 | | |
| Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched | | |
| Jitsuyo Shinan Koho 1926 - 1997 Kokai Jitsuyo Shinan Koho 1971 - 1997 Toroku Jitsuyo Shinan Koho 1994 - 1997 | | |
| Electronic data base consulted during the international search (name of data base and, where practicable, search terms used) | | |
| C. DOCUMENTS CONSIDERED TO BE RELEVANT | | |
| Category* | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
| X | JP, 6-195747, A (NEC Corp.), July 15, 1994 (15. 07. 94) (Family: none) | 1 - 35 |
| X | JP, 5-217211, A (Ricoh Co., Ltd.), August 27, 1993 (27. 08. 93) (Family: none) | 1 - 35 |
| X | JP, 3-104038, A (Asahi Chemical Industry Co., Ltd.), May 1, 1991 (01. 05. 91) (Family: none) | 1 - 35 |
| X | JP, 3-40244, A (NEC Corp.), February 21, 1991 (21. 02. 91) (Family: none) | 1 - 35 |
| X | JP, 7-21583, A (Asahi Chemical Industry Co., Ltd.), January 24, 1995 (24. 01. 95) (Family: none) | 4, 9, 11, 13, 15, 16, 21-24 |
| X | JP, 4-78032, A (Toshiba Corp.), March 12, 1992 (12. 03. 92) (Family: none) | 36 - 53 |
| X | JP, 5-62193, A (Matsushita Electric Industrial | 54 - 57 |
| <input checked="" type="checkbox"/> Further documents are listed in the continuation of Box C. <input type="checkbox"/> See patent family annex. | | |
| <p>* Special categories of cited documents:</p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"E" earlier document but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p> <p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone</p> <p>"Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art</p> <p>"&" document member of the same patent family</p> | | |
| Date of the actual completion of the international search | | Date of mailing of the international search report |
| July 8, 1997 (08. 07. 97) | | July 23, 1997 (23. 07. 97) |
| Name and mailing address of the ISA/ Japanese Patent Office | | Authorized officer |
| Facsimile No. | | Telephone No. |
